## 2. Crosslinking density according to Flory-Rehner

The following information provides further insight into the calculation of the cross-linking density (equation S1)

$$v_{cross}(\text{mol g}^{-1}) = -\frac{\ln(1-v_r) + v_r + \chi v_r^2}{2\rho_r V_s (\sqrt[3]{v_r} - \frac{v_r}{2})}, \quad (\text{S1})$$

The volume fraction of the equilibrium swollen rubber  $v_r$  was calculated according to equation S2:

$$v_r = \frac{\frac{w_0 - w_F}{\rho_{r0}}}{\frac{w_0 - w_F}{\rho_{r0}} + \frac{w_{eq} - w_0}{\rho_S}} \quad (\text{S2})$$

where  $w_0$  in g is the weight of the nanocomposite sample before the sorption measurement,  $w_{eq}$  is the weight of the same sample after reaching the equilibrium sorption mass,  $w_F$  is the weight of the filler (calculated by  $w_0$  multiplied by the filler content in wt.-%, as the sum of ZnO, CB and FLG),  $\rho_{r0}$  is the density of the unfilled rubber sample (with 0 phr FLG content) and  $\rho_S$  is the density of the solvent isoctane ( $0.69 \text{ g cm}^{-3}$ ).  $\chi$  is the Flory-Huggings parameter, at 0.49 for isoctane and natural rubber.
