ABSTRACT

Objective The interleukin 2 (IL-2) and interleukin 21 (IL-21) locus at chromosome 4q27 has been associated with several autoimmune diseases, and both genes are related to immune system functions. The aim of this study was to evaluate the role of the IL-2/IL-21 locus in systemic sclerosis (SSc).

Patients and methods The case control study included 4493 SSc Caucasian patients and 5856 healthy controls from eight Caucasian populations (Spain, Germany, The Netherlands, USA, Italy, Sweden, UK and Norway). Four single nucleotide polymorphisms (rs2069762, rs6822844, rs6835457 and rs907715) were genotyped using TaqMan allelic discrimination assays.

Results We observed evidence of association of the rs6822844 and rs907715 variants with global SSc (pc=6.6E-4 and pc=7.2E-3, respectively). Similar statistically significant associations were observed for the limited cutaneous form of the disease. The conditional regression analysis suggested that the most likely genetic variation responsible for the association was the rs6822844 polymorphism. Consistently, the rs2069762A-rs6822844T-rs6835457G-rs907715T allelic combination showed evidence of association with SSc and limited cutaneous SSc subtype (pc=1.7E-03 and pc=8E-4, respectively).

Conclusions These results suggested that the IL-2/IL-21 locus influences the genetic susceptibility to SSc. Moreover, this study provided further support for the IL-2/IL-21 locus as a common genetic factor in autoimmune diseases.

INTRODUCTION

Interleukin 2 (IL-2) and interleukin 21 (IL-21) are equally attractive biological candidates that may influence the pathogenesis of autoimmune diseases. Both are cytokines involved in the proliferation of T and B lymphocytes and different immunological activation pathways. Moreover, the IL-2 and IL-21 genes cover a region of approximately 200 kb that maps in the 4q27 locus. IL-2 has an important role in the maintenance of immune system homeostasis and self-tolerance. This cytokine has two paradoxical roles: promoting T cell proliferation and terminating T cell responses. Moreover, IL-2 facilitates the production of immunoglobulins through B cells and induces the differentiation and proliferation of natural killer cells.1 2 IL-21 is a potent immunomodulatory cytokine with pleiotropic effects on both innate and adaptive immune responses. These actions include the following positive effects: enhanced proliferation of lymphoid cells, increased cytotoxicity of CD8 T cells and natural killer cells, and differentiation of B cells into plasma cells. IL-21 is also produced by T helper 17 (Th17) cells and is a critical regulator of Th17 development.3 4 Genetic association studies have demonstrated that several IL-2/IL-21 polymorphisms influence the risk for autoimmune diseases (AIDs). The first evidence of this association was found in type 1 diabetes, Graves’ disease, coeliac diseases and rheumatoid arthritis.4 7 These results have been confirmed through replication studies in different populations and extended to other autoimmune diseases, such as inflammatory bowel diseases, giant cell arthritis, psoriasis and systemic lupus erythematosus (SLE).8–17

Systemic sclerosis (SSc) is a chronic fibrotic autoimmune disease in which patients are commonly classified into the following two major subgroups that are related to the specific autoantibodies against several nuclear and/or nucleolar antigens: (i) limited cutaneous SSc (lcSSc), which is related to the positive status of anti-centromere autoantibodies (ACA) and (ii) diffuse cutaneous (dcSSc), which is related to the positive status of antitopoisoenzyme...
autoantibodies (ATA). More than 40 susceptibility loci to SSC have been identified during the last 10 years. Half of these variants need to be replicated in different populations and many of these variants are shared among different AIDs, especially SLE. In this regard, one single nucleotide polymorphism (SNP) of the IL-2 region is implicated in the genetic susceptibility to SLE.22–25 Moreover, the IL-21 region has been implicated as a potential driver of AIDs and recently a fine-mapping in SLE demonstrated that variants of the IL-2/IL-21 region are implicated in the genetic susceptibility to SLE. Thus, the aim of this study was to evaluate the influence of the IL-2/IL-21 region in SSC genetic susceptibility.

**PATIENTS AND METHODS**

**Subjects**

This case-control association study was comprised of 4493 SSC patients and 5896 controls of Caucasian ancestry. The discovery cohort included the Spanish group, which consisted of 1176 SSC patients and 1721 healthy controls. The follow-up phase consisted of the following subjects: 609 SSC cases and 426 controls from Germany, 365 SSC cases and 754 controls from the Netherlands, 916 SSC cases and 884 controls from USA, 595 SSC cases and 1107 controls from Italy, 225 SSC cases and 273 controls from Sweden, 374 SSC cases and 456 controls from the UK and 102 SSC cases and 278 controls from Norway. There was an overlapping of 1726 SSC and 2578 controls with the previous GWAS in SSC. The patients fulfilled the 1980 American College of Rheumatology classification criteria for SSC or the criteria proposed for early SSC. In addition, the patients were classified as having lcSSc or dcSSc as described by LeRoy et al.

The following clinical data were collected for the ascertainment of the clinical phenotype of the SSC patients: age, gender and presence of SSC-specific autoantibodies (Ab; ACA and ATA). The control population consisted of unrelated healthy individuals recruited in the same geographical regions as the SSC patients, and they were matched by age, sex and ethnicity with the SSC patient groups. The study was approved by local ethical committees from all the participating centres. Both patients and controls were included in the study after written informed consent was obtained.

**SNP Selection and genotyping**

Four SNPs of the IL-2/IL-21 region were selected for this study. The rs2069762 SNP was selected because it has been proposed as risk factor to lcSSc subtype, but this association has not been confirmed by other studies. Moreover the IL-21 gene has been implicated as a potential driver of AIDs and recently a fine-mapping in SLE demonstrated that variants of the IL-2/IL-21 region are implicated in the genetic susceptibility to SLE. Thus, the aim of this study was to evaluate the influence of the IL-2/IL-21 region in SSC genetic susceptibility.

**RESULTS**

The cases and controls of the eight Caucasian populations were in Hardy-Weinberg equilibrium at a 5% significance level. Additionally, the minor allelic frequencies of the four studied SNPs were similar to those reported by the HapMap project for the Utah residents with ancestry from northern and western Europe (CEU) population (http://hapmap.ncbi.nlm.nih.gov/). The LD structure of the eight cohorts is shown in the supplementary material (see online supplementary figure S1).

First, an association study was conducted in a Spanish case-control set, and a significant association was observed between the rs907715 SNPs minor allele and the global SSC (p=0.03, OR=0.85 95% CI 0.8 to 0.9) and the lcSSc subtype (p=0.04, OR=0.83 95% CI 0.7 to 0.9). A trend of association was observed between the minor allele of the rs6822844 SNP and the global SSC (p=0.04, OR=0.84 95% CI 0.7 to 1) and lcSSc subtype (p=0.04, OR=0.79 95% CI 0.7 to 0.9). Also a trend of association was detected between the minor allele of rs6835457 and lcSSc subtype in this population (p=0.03, OR=0.87 95% CI 0.8 to 1). In contrast, no association was observed with the rs2069762 SNP (p=0.8 for both SSC and lcSSc) (see online supplementary tables S1–S3).

Table 1 shows the meta-analysis results for the IL-2/IL-21 SNPs, the global SSC, the main SSC subtypes, the ACA and the ATA antibodies positive status. The combined analysis showed that the minor allele frequencies of the rs6822844 and rs907715 SNPs were significantly higher in controls than in SSC (p=0.04 OR=0.86 95% CI 0.79 to 0.93 and p=0.04 OR=0.83 95% CI 0.8 to 0.9, respectively).
and lcSSc patients (p_c=6E-4 OR=0.84 95% CI 0.76 to 0.92 and p_c=0.01 OR=0.9 95% CI 0.84 to 0.96, respectively). A trend of association was observed in the meta-analysis for the rs6822844 and rs6835457 variants and ACA positive status (p_value=0.01 OR=0.87 95% CI 0.78 to 0.97 and p_value=0.05 OR=0.92 95% CI 0.85 to 1, respectively). The rs6835457 SNP also had a trend of association with global SSc and lcSSc (p_value=0.01 OR=0.93 95% CI 0.87 to 0.98 and

ACA, anticientromere autoantibodies; lcSSC, limited cutaneous SSc; MAF, minor allelic frequencies; SNP, single nucleotide polymorphisms; SSc, systemic sclerosis.

p-value=0.01 OR=0.92 95% CI 0.86 to 0.98, respectively). We did not detect any significant association between the rs6835457 or rs2069762 SNPs and the global SSc diseases or its different phenotypes (for detailed information see supplementary tables S1 through S3). It is worth noting that the minor I² percentage was observed in the meta-analysis for the rs6822844 SNP with SSc (17.3%) and lcSSc (33.9%), suggesting that the variation between the populations is moderate. Moreover, these analyses were the only ones that remained significant in the random-effect model (rs6822844 and SSc p-value=3.5E-3, OR=0.89 95% CI 0.81 to 0.98), the lcSSc subtype increased in the controls compared with the global SSc susceptibility to SSc. This variant also in observed in the suggested that the rs907715 signal could explain the association when conditioned to the rs6822844 SNP. These results suggest that the rs6822844 signal could explain the association observed in the IL-2/-IL-21 locus (table 2).

Finally, the results of the conditional haplotype-based association testing are shown in table 3. The allelic combination formed by the rs2069762 major allele and the rs6822844, rs6835457 and rs907715 minor alleles was significantly increased in the controls compared with the global SSc (p-value=1.7E-3, OR=0.89 95% CI 0.81 to 0.98), the lcSSc subtype (p-value=8E-4, OR=0.86 95% CI 0.77 to 0.96) and the ACA positive status (p-value=2.7E-2, OR=0.86 95% CI 0.75 to 0.98). Interestingly, the OR observed for this analysis was not different from the one observed in the allelic test. Moreover, the significant effect of the omnibus analyses for SSc, lcSSc and ACA positive status disappeared when they were controlled by the rs6822844 SNP (p-values of the likelihood ratio test were: p-value=0.66 for global SSc, p-value=0.74 for lcSSc and p-value=0.93 for ACA+).

DISCUSSION

Our study suggests for the first time the influence of the rs6822844 polymorphism of the IL-2/-IL-21 region in susceptibility to SSc. This variant also influences the lcSSc subtype of the diseases and probably the ACA positive status due to the trend of association observed between the rs6822844 polymorphism and this phenotype. Although, our study had sufficient statistical power for both dcSSc and ATA analysis (95% and 91%, respectively), we observed that there were not significant associations between the four IL-2/-IL-21 SNPs and dcSSc or ATA positive status. The ORs exhibited the same direction as the significant associations with SSc and lcSSc, suggesting that an increment in the sample size with future studies could show a significant relation between the IL-2/-IL-21 SNPs and dcSSc or ATA. Interestingly, the rs6822844 variant was associated in the same OR direction as that observed in SLE. The minor allele of this variant is more frequent in healthy donors than in SSc patients, lcSSc subtype subjects and SLE patients.12 16 The logistic regression and the allelic combination analyses support that the rs6822844 SNP association was responsible for the observed associations. The rs2069762A-rs6822844T-rs6835457G-rs907715T allelic combination was associated as a protective factor to SSc, lcSSc subtype and ACA positive status, which is the same effect observed for the T allele of the rs6822844. Importantly, the ORs observed for this allelic combination were not different from the ORs observed for the rs6822844 SNP analysis. These observations were slightly different from the results of the SLE study performed by Hughes et al. where the observed association between IL-2/-IL-21 region and SLE could be explained by the rs6835457 and rs907715 SNPs. Together, these results support the idea that the common genetic factors in autoimmune diseases may be associated at a regional level but differ in the specific SNPs associated with each disease, including the magnitude and direction of the association.31 32 Although, the logistic regression test and the allelic combination analyses conditioned by the rs6822844 SNP suggest that this variant is responsible for the association observed in the region; we cannot totally discard a slight role of the rs6835457 and rs907715 polymorphisms in SSc due to the moderate LD between them and the rs6822844 SNP. The rs6822844 and rs6835457 SNPs are located in the flanking 5′-untranslated region of IL-21, and the rs907715 polymorphism is located in intron 3 of the IL-21 gene. In contrast, the rs2069762 SNP is located in the flanking 5′-untranslated region of IL-2, which did not exhibit significant association with SSc, the subtypes of the disease or the antibodies’ status. The rs2069762 minor allele has been previously associated with SSc, the subtypes of the disease or the antibodies

significant association for rs2069762 might stem from type 1 statistical error. This fact together with the location of the associated SNP suggests a heightened role of the IL-21 cytokine. By examining the expression and regulation of IL-21 and the IL-21 receptor (IL-21R) in patients with SSc, a previous study demonstrated an upregulation of IL-21R in epidermis samples. However, a recent study has demonstrated that the scleroderma burden in allogeneic haemopoietic stem cell transplantations is driven by Th17 induction via IL-21 and IL-23 signalling. Together, these results suggest that IL-21/IL-21R signalling has a pathogenic function in SSc.

The role of IL-2 and IL-21 in the immune system makes these genes plausible candidates for the genetic component of autoimmune diseases. Our results increase the evidence that have shown that the rs6822844 is significantly associated with multiple autoimmune diseases. According to the HapMap project for the CEU population (http://hapmap.ncbi.nlm.nih.gov/), the rs68284 polymorphism tags seven other variants located along the IL-2/IL-21 region (rs13123245, rs13122573, rs4459999, rs1519161, rs15140464, rs6141280 and rs2069778), but clear evidence that connects any of these variants with the IL-2 and/or IL-21 regulation is lacking. Together, all point out these genetic variants as good candidates for functional studies in SSc pathogenesis and in other autoimmune diseases.

Although, the combined analyses of the rs6822844 polymorphism did not show heterogeneity (BD P-value = 0.29, I² = 17.8%) between the eight European populations, a weak point of our study is that we did not have enough data available to control the association by principal component. Furthermore, as we mentioned before, an increment in the sample size for the stratified analysis could define in an accurate way the role of the studied variants in different clinical manifestations of SSc as their influence in the presence of coautoimmunity. Consequently, it is necessary to replicate the actual observation.

To conclude, consistent with previous studies on autoimmune diseases, the IL-2/IL-21 region is a susceptibility genetic factor for SSc and its lcsSsc subtype. The rs6822844 polymorphism confers the best association signal for SSc. It is also worth mentioning that this study shows the importance of the study of different populations and broad collaboration to find the missing heritability for relatively rare diseases like SSc.
