Abstract

With an emphasis on generators with quadratic growth in the control variable we consider measure solutions of BSDE, a solution concept corresponding to the notion of risk neutral measure in mathematical finance. In terms of measure solutions, solving a BSDE reduces to martingale representation with respect to an underlying filtration. Measure solutions related to measures equivalent to the historical one provide classical solutions. We derive the existence of measure solutions in scenarios in which the generating functions are just continuous, of at most linear growth in the control variable (corresponding to generators of at most quadratic growth in the usual sense), and with a random bound in the time parameter whose stochastic integral is a BMO martingale. Our main tools include a stability property of sequences of measure solutions, for which a limiting solution is obtained by means of the weak convergence of measures.

Key words and phrases: backward stochastic differential equation; BSDE; measure solution; minimal solution; theorem of Girsanov; weak convergence of probability measures; minimal solution; comparison; BMO martingale.

Introduction

The most efficient formulation of pricing and hedging contingent claims on complete financial markets is given by the elegant notion of risk neutral or martingale measures. From its perspective, pricing amounts to taking expectations, while hedging boils down to pure conditioning and using martingale representation.

From the perspective of stochastic control theory, hedging consists in choosing appropriate strategies to steer a portfolio into a terminal random endowment the portfolio holder has to ensure. Backward stochastic differential equations (BSDE) are tailor-made for this purpose. On a Brownian basis, a BSDE with terminal variable ξ at time horizon T and generator f is solved by a pair of processes (Y, Z) on the interval $[0, T]$ satisfying

$$Y_t = \xi - \int_t^T Z_s dW_s + \int_t^T f(s, Y_s, Z_s) ds, \quad t \in [0, T]. \quad (1)$$

In case $f = 0$, the solution just requires an application of the martingale representation theorem, and Z will be given as the stochastic integrand therein. Generators f in BSDE derived from many problems of utility maximization or risk minimization turn out to be quadratic in the control variable z , and have been treated in a large number of papers starting with the pioneering one by Kobylanski [18].

In [3], the notion of *measure solutions* for BSDE has been introduced with the aim to extend the passage from the historical to the risk neutral world to a more general framework. In analogy with martingale measures in hedging which eliminate drifts in the underlying market dynamics, these solutions of BSDE are given by probability measures under which their generators are seen as vanishing. Determining a measure \mathbb{Q} under which the generator vanishes amounts to performing a Girsanov change of probability that eliminates it. We therefore have to look at the BSDE in the form

$$Y_t = \xi - \int_t^T Z_s [dW_s - g(s, Y_s, Z_s)ds], \quad t \in [0, T], \quad (2)$$

where $z \cdot g(s, y, z) = f(s, y, z)$, and study the measure

$$\mathbb{Q} = \exp \left(M_T - \frac{1}{2} \langle M \rangle_T \right) \cdot \mathbb{P}$$

for the martingale $M = \int_0^\cdot g(s, Y_s, Z_s) dW_s$. Supposing that such a measure \mathbb{Q} is equivalent to the historical measure \mathbb{P} , the classical solution pair (Y, Z) results from projection and representation respectively, i.e.

$$Y = \mathbb{E}^{\mathbb{Q}}[\xi | \mathcal{F}_\cdot] = Y_0 + \int_0^\cdot Z_s d\tilde{W}_s \quad (3)$$

where \tilde{W} is a Wiener process under \mathbb{Q} . It is known from [3] that basically all classical solutions can be interpreted as measure solutions.

In this paper we view measure solutions still more generally as probability measures \mathbb{Q} related to terminal variables ξ and *generating functions* g such that the operation of projection and representation providing the pair of processes (Y, Z) according to (3) leads to an interpretation of the exponential martingale density ζ in

$$\frac{d\mathbb{Q}}{d\mathbb{P}} = \exp \left(\int_0^T \zeta_s dW_s - \frac{1}{2} \int_0^T \zeta_s^2 ds \right)$$

by

$$\zeta = g(\cdot, Y, Z).$$

Obviously, in case $\mathbb{Q} \sim \mathbb{P}$ this notion allows to identify (Y, Z) as the classical solution of (1) related to the *generator* $f(\cdot, z) = z \cdot g(\cdot, z)$, since

$$Y = Y_0 + \int_0^\cdot Z_s [dW_s - \zeta_s ds] = Y_0 + \int_0^\cdot Z_s dW_s - \int_0^\cdot f(s, Y_s, Z_s) ds.$$

Note that a generator f which is quadratic in z corresponds to a generating function g which is of at most linear growth in z . Our main aim is to provide a result on the existence of a measure solution (and thus a classical one) in a scenario in which the terminal variable is bounded, the generating function g is just continuous off the hyperplane $z = 0$ and fulfills the rather general boundedness hypothesis $|g(s, \cdot, z)| \leq C(|z| + \phi_s)$, where the stochastic integral

of ϕ with respect to W is a BMO martingale. Note that in this scenario the bound on g may be random, a detail which turned out to be of considerable practical relevance for example in [1] and [2]. The main tool we develop in order to reach this goal consists in a stability property for measure solutions. Given a sequence of measure solutions $(\mathbb{Q}_n)_{n \in \mathbb{N}}$ associated with terminal conditions and generating functions given by $(\xi_n, g_n)_{n \in \mathbb{N}}$, we formulate sufficient conditions under which a limiting measure solution can be found, as a weak limit of the sequence $(\mathbb{Q}_n)_{n \in \mathbb{N}}$. Given a generating function in the situation of our main existence theorem, the sequence of approximating measure solutions is constructed along smoothed approximations of the generating function, obtained by a new technique based on comparison properties of classical minimal solutions. Owing to the boundedness conditions valid for the generating function g , BMO martingale techniques play an important role in our reasoning.

The paper is organized as follows. In section 1, we explain the notion of measure solution and a slight modification of it, the *almost-measure solution*. In section 2, our main result on the stability of measure solutions is established in a technical proof based on tools related to the weak convergence of probability measures and the martingale representation of their Radon-Nikodym densities (Theorems 2.1 and 2.2). This result is combined with comparison related tools in section 3 to prove our main statement on the existence of measure and classical solutions of BSDE (Theorem 3.1). In an appendix we collect some (extensions of) well known results about BMO martingales, martingale representation and duality in normed spaces.

1 Preliminaries

Let $(\Omega, \mathcal{F}_T, \mathbb{P}, (\mathcal{F}_t)_{t \in [0, T]})$ be a filtered probability space, such that the filtration satisfies the usual hypotheses. Assume furthermore there exists a d -dimensional Brownian motion W on $[0, T]$, which is progressive with respect to $(\mathcal{F}_t)_{t \in [0, T]}$ and such that $\mathcal{F}_t = \mathcal{F}_t^W$, the natural filtration generated by W (and augmented by the null sets).

Define for $q \geq 1$ and any probability measure \mathbb{Q} the set $\mathcal{H}^q(\mathbb{R}^m, \mathbb{Q})$ as the space of all progressive processes $(Z_t)_{t \in [0, T]}$ with values in \mathbb{R}^m normed by $\|Z\|_{\mathcal{H}^q} := \mathbb{E}_{\mathbb{Q}} \left[\left(\int_0^T |Z_s|^2 ds \right)^{\frac{q}{2}} \right]^{\frac{1}{q}} < \infty$.

Let $\mathbb{Q} \sim \mathbb{P}$ be a probability measure. Define $R_T := \frac{d\mathbb{Q}}{d\mathbb{P}}$ as the Radon-Nikodym derivative. Then the martingale $R := \mathbb{E}[R_T | \mathcal{F}_\cdot]$ can be written as $R = \exp \left(\int_0^\cdot \zeta_s dW_s - \frac{1}{2} \int_0^\cdot |\zeta_s|^2 ds \right)^1$ with some progressively measurable process ζ such that $\int_0^T |\zeta_s|^2 ds < \infty$ a.s. (Lemma A.5).

Define

$$W^{\mathbb{Q}} := W - \int_0^\cdot \zeta_s ds. \quad (4)$$

Then $W^{\mathbb{Q}}$ is a Brownian motion with respect to \mathbb{Q} according to Girsanov's Theorem. It is well known (e.g. Lemma 1.6.7 in [16]) that $W^{\mathbb{Q}}$ has the representation property in $(\mathcal{F}_t)_{t \in [0, T]}$, i.e. for any real-valued \mathcal{F}_T -measurable ξ , which is integrable with respect to \mathbb{Q} , we have

$$\xi = \mathbb{E}_{\mathbb{Q}}[\xi] + \int_0^T Z_s dW_s^{\mathbb{Q}} \quad (5)$$

with some progressively measurable process Z such that $\int_0^T |Z_s|^2 ds < \infty$ a.s. Define $Y_t := \mathbb{E}_{\mathbb{Q}}[\xi | \mathcal{F}_t]$ for all $t \in [0, T]$.

¹ $\zeta_s dW_s = \zeta_s \cdot dW_s$ stands for the scalar product between the vectors ζ_s and dW_s . It is used as an abbreviation for the notation $\zeta_s^\top dW_s$.

Definition 1.1. We call a function

$$f : \Omega \times [0, T] \times \mathbb{R}^n \rightarrow \mathbb{R}^m$$

proper if f restricted to $\Omega \times [0, t] \times \mathbb{R}^n$ is $\mathcal{F}_t \otimes \mathcal{B}([0, t]) \otimes \mathcal{B}(\mathbb{R}^n)$ -measurable for all $t \in [0, T]$.

If f is proper and X is a progressive \mathbb{R}^n -valued process, then the process $(\omega, s) \mapsto f(\omega, s, X_s(\omega))$ is progressive as well. This is because the mapping

$$\Omega \times [0, t] \rightarrow \Omega \times [0, t] \times \mathbb{R}^n$$

$$(\omega, s) \mapsto (\omega, s, X_s(\omega))$$

is $\mathcal{F}_t \otimes \mathcal{B}([0, t]) - \mathcal{F}_t \otimes \mathcal{B}([0, t]) \otimes \mathcal{B}(\mathbb{R}^n)$ - measurable for all $t \in [0, T]$. The following definition presents the principal concept of this paper.

Definition 1.2. For a given probability measure $\mathbb{Q} \sim \mathbb{P}$ and $\xi \in L^1(\mathcal{F}_T, \mathbb{Q})$, let ζ , Z and Y be as above. Now let

$$g : \Omega \times [0, T] \times \mathbb{R} \times \mathbb{R}^d \rightarrow \mathbb{R}^d$$

be proper. We say that \mathbb{Q} is a measure solution of the BSDE given by g and ξ if

$$\zeta = g(\cdot, Y, Z) \quad d\mathbb{P} \otimes dt \text{ - a.e.}$$

Remark 1.3. Inserting this definition into (4) and the result into (5) we have

$$\xi = \mathbb{E}_{\mathbb{Q}}[\xi] + \int_0^T Z_s dW_s - \int_0^T Z_s \cdot g(s, Y_s, Z_s) ds.$$

And similarly using $Y = \mathbb{E}_{\mathbb{Q}}[\xi | \mathcal{F}_\cdot] = Y_0 + \int_0^\cdot Z_s dW_s^{\mathbb{Q}}$ we have

$$Y = Y_0 + \int_0^\cdot Z_s dW_s - \int_0^\cdot Z_s \cdot g(s, Y_s, Z_s) ds.$$

Thus (Y, Z) is also a classical solution of the BDSE given by the generator f satisfying

$$f(s, y, z) := z \cdot g(s, y, z), \quad s \in [0, T], z \in \mathbb{R}^d, y \in \mathbb{R},$$

and the terminal condition $Y_T = \xi$.²

In the following lemma we characterize generators f which can be written in the form $f(t, y, z) = z \cdot g(t, y, z)$, $t \in [0, T]$, $y \in \mathbb{R}$, $z \in \mathbb{R}^d$, with some continuous g .

Lemma 1.4. Let $f : \mathbb{R}^d \rightarrow \mathbb{R}$ be continuous. There exists some continuous $g : \mathbb{R}^d \rightarrow \mathbb{R}^d$ such that for $z \in \mathbb{R}^d$ we have $f(z) = z \cdot g(z)$ if and only if the following two conditions are satisfied:

- $f(0) = 0$,
- f is differentiable at 0.

² $z \cdot g(s, y, z)$ stands for the scalar product of z and $g(s, y, z)$, which sometimes will be abbreviated simply by $zg(s, y, z)$.

Proof. Let g be continuous such that for $z \in \mathbb{R}^d$ we have $f(z) = z \cdot g(z)$. Then $f(0) = 0 \cdot g(0) = 0$. Furthermore

$$\frac{1}{|z|} |f(z) - f(0) - z \cdot g(0)| = \frac{1}{|z|} |z \cdot (g(z) - g(0))| \leq |g(z) - g(0)| \rightarrow 0 \text{ as } z \rightarrow 0$$

which means that f is differentiable at 0 with $\nabla_z f(0) = g(0)$.

Conversely let f be differentiable at 0 and $f(0) = 0$. Define

$$g(z) := \frac{z}{|z|^2} (f(z) - z \cdot \nabla_z f(0)) + \nabla_z f(0)$$

for $z \neq 0$ and $g(0) := \nabla_z f(0)$. Since

$$\left| \frac{z}{|z|^2} (f(z) - z \cdot \nabla_z f(0)) \right| = \frac{1}{|z|} |f(z) - f(0) - z \cdot \nabla_z f(0)| \rightarrow 0 \text{ as } z \rightarrow 0$$

due to differentiability of f at 0, g is continuous at 0 and hence everywhere. Finally we have for $z \in \mathbb{R}^d$

$$z \cdot g(z) = \frac{|z|^2}{|z|^2} (f(z) - z \cdot \nabla_z f(0)) + z \cdot \nabla_z f(0) = f(z).$$

□

Definition 1.5. For a given probability measure $\mathbb{Q} \sim \mathbb{P}$ and $\xi \in L^1(\mathcal{F}_T, \mathbb{Q})$ let ζ , Z and Y be defined as in section 1. Let

$$g : \Omega \times [0, T] \times \mathbb{R} \times \mathbb{R}^d \rightarrow \mathbb{R}^d$$

be proper. We say that \mathbb{Q} is an almost measure solution (*a.-measure solution*) of the BSDE given by g and ξ if

$$\zeta \mathbf{1}_{\{Z \neq 0\}} = g(\cdot, Y, Z) \mathbf{1}_{\{Z \neq 0\}} \quad d\mathbb{P} \otimes dt - a.e.$$

Remark 1.6. Obviously measure solutions are always *a.-measure solutions*.

Substituting the definition of an *a.-measure solution* into (4) and the result into (5) we have

$$\xi = \mathbb{E}_{\mathbb{Q}}[\xi] + \int_0^T Z_s dW_s - \int_0^T Z_s \cdot g(s, Y_s, Z_s) ds.$$

And similarly using $Y_t = \mathbb{E}_{\mathbb{Q}}[\xi | \mathcal{F}_t] = Y_0 + \int_0^t Z_s dW_s^{\mathbb{Q}}$ we have

$$Y_t = Y_0 + \int_0^t Z_s dW_s - \int_0^t Z_s \cdot g(s, Y_s, Z_s) ds, \quad t \in [0, T].$$

Thus (Y, Z) is also a classical solution of the BDSE given by the generator f which satisfies

$$f(s, y, z) = z \cdot g(s, y, z), \quad s \in [0, T], y \in \mathbb{R}, z \in \mathbb{R}^d,$$

and the terminal condition $Y_T = \xi$.

Remark 1.7. If there is a proper \hat{g} , which might differ from g , but satisfies $z \cdot \hat{g}(\cdot, z) = z \cdot g(\cdot, z)$ and if for $\hat{\zeta} := \hat{g}(\cdot, Y, Z)$ the measure $\hat{\mathbb{Q}} := \mathcal{E}(\hat{\zeta} \bullet W)_T \cdot \mathbb{P}$ is a probability measure satisfying $\mathbb{E}_{\hat{\mathbb{Q}}}[\|\xi\|] < \infty$, then it must be already a *measure solution* of the BSDE given by \hat{g} and ξ . In fact, for $t \in [0, T]$ we have

$$Y_t = \mathbb{E}_{\mathbb{Q}}[\xi] + \int_0^t Z_s dW_s - \int_0^t Z_s \cdot g(s, Y_s, Z_s) ds =$$

$$= \mathbb{E}_{\mathbb{Q}}[\xi] + \int_0^t Z_s dW_s - \int_0^t Z_s \cdot \hat{\zeta}_s ds = \mathbb{E}_{\mathbb{Q}}[\xi] + \int_0^t Z_s dW_s^{\hat{\zeta}}$$

where $W_t^{\hat{\zeta}} := W_t - \int_0^t \hat{\zeta}_s ds$ is a Brownian motion with respect to $\hat{\mathbb{Q}}$. Hence $\hat{Y}_t := \mathbb{E}_{\hat{\mathbb{Q}}}[\xi | \mathcal{F}_t] = \mathbb{E}_{\hat{\mathbb{Q}}}[Y_T | \mathcal{F}_t] = \mathbb{E}_{\mathbb{Q}}[\xi] + \int_0^t Z_s dW_s^{\hat{\zeta}} = Y_t$ and $\hat{Z} = Z$. Therefore $\hat{\zeta} = \hat{g}(\cdot, \hat{Y}, \hat{Z})$ and so $\hat{\mathbb{Q}}$ is indeed a measure solution.

In most cases we will set $\hat{g} := g$.

2 Stability Results

In this section we shall consider stability properties of the measure solution concept. More formally, we shall look at sequences of measure solutions related to sequences of terminal conditions and generators, and provide answers to the question: under which additional conditions concerning these model parameters will an eventually existing weak limit measure describe a measure solution. We shall find sufficient conditions for this to hold, including uniform L^p -boundedness of the Radon-Nikodym derivatives of the sequence of measures, and suitable convergence properties for the sequences of terminal conditions and generators. Our main results are given by the following two technical theorems.

Theorem 2.1. *Let $(\mathbb{Q}_n)_{n \in \mathbb{N}}$ be a sequence of measures, such that for any $n \in \mathbb{N}$, \mathbb{Q}_n describes a measure solution of the BSDE given by some proper g_n and $\xi_n \in L^0(\mathcal{F}_T)$ and let Y^n, Z^n correspond to \mathbb{Q}_n and ξ_n in the sense of section 1. Let $p, q > 1$ such that $1/p + 1/q = 1$ and assume the following:*

i)

$$\sup_n \mathbb{E} \left[\left(\frac{d\mathbb{Q}_n}{d\mathbb{P}} \right)^p \right] < \infty, \quad \sup_n \mathbb{E}_{\mathbb{Q}_n} \left[\left(\frac{d\mathbb{P}}{d\mathbb{Q}_n} \right)^q \right] < \infty;$$

ii) $\xi_n \rightarrow \xi$ as $n \rightarrow \infty$ in $L^{2q}(\mathbb{P})$ and $\xi \in L^{2q}(\mathbb{P})$;

iii) Y^n converges in $\mathcal{H}^q(\mathbb{R}, \mathbb{P})$ to some $\tilde{Y} \in \mathcal{H}^q(\mathbb{R}, \mathbb{P})$ for $n \rightarrow \infty$;

iv) $\lim_{n \rightarrow \infty} g_n(\omega, s, \cdot, \cdot) = g(\omega, s, \cdot, \cdot)$ uniformly on compact sets $K \ni (y, z)$ for a.a. (ω, s) , with g proper and continuous in (y, z) for a.a. (ω, s) .

Then $(\mathbb{Q}_n)_{n \in \mathbb{N}}$ converges "weakly" to a probability measure \mathbb{Q} in the sense

$$\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n}[X] = \mathbb{E}_{\mathbb{Q}}[X] \quad \forall X \in L^q(\mathbb{P}), \quad (6)$$

and \mathbb{Q} is a measure solution of the BSDE given by g and ξ .

Before we prove this result, let us discuss conditions i)-iv):

Conditions ii) and iv) essentially mean that the approximating BSDE should converge to the limiting BSDE in some sense.

Condition i) can be seen as a compactness criterion. It stipulates that the p -norms of the Radon-Nikodym-derivatives of the measure change between \mathbb{Q}_n and \mathbb{P} should be uniformly bounded in n in both "directions". This control is essential to conclude the existence of a cluster point \mathbb{Q} which will later be shown to be a limit.

Condition iii) is necessary to conclude convergence of the sequence of measure solutions. It can be shown later that \tilde{Y} must be the Y -process of the measures solution of the limiting BSDE. When applying the Theorem, condition iii) will usually be verified by choosing for

a given pair (g, ξ) the approximating (g_n, ξ_n) in such a way that the associated generators $f_n(\cdot, z) := z \cdot g_n(\cdot, z)$, $z \in \mathbb{R}^d$, as well as the terminal conditions ξ_n are chosen from a monotonically increasing or decreasing sequence. This allows to apply the comparison theorem to conclude monotonicity of the Y^n , which in turn will imply their convergence in $\mathcal{H}^q(\mathbb{R}, \mathbb{P})$ by means of dominated convergence.

Proof of Theorem 2.1. For $n \in \mathbb{N}$ let $R_T^n := \frac{d\mathbb{Q}_n}{d\mathbb{P}}$. Then $(R_T^n)_{n \in \mathbb{N}}$ is a bounded sequence in $L^p(\mathbb{P}) = L^p(\mathcal{F}_T, \mathbb{P})$ according to *i*).

Firstly we claim, that in order to prove the theorem it is actually sufficient to show that all subsequences of $(\mathbb{Q}_n)_{n \in \mathbb{N}}$ possess a particular probability measure \mathbb{Q} as a cluster point (with respect to convergence figuring in (6)) and that this measure \mathbb{Q} is a measure solution of the BSDE given by g and ξ .

In fact, assume that this is the case. Let $X \in L^q(\mathbb{P})$. Then $\mathbb{E}_{\mathbb{Q}_n}[X] = \mathbb{E}[R_T^n X]$, $n \in \mathbb{N}$, is a bounded sequence by Hölder's inequality. Hence there exists a subsequence $(\mathbb{Q}_{n_k})_{k \in \mathbb{N}}$ such that $\mathbb{E}_{\mathbb{Q}_{n_k}}[X]$ converges to the superior limit of the sequence. But then for a subsequence of $(\mathbb{Q}_{n_k})_{k \in \mathbb{N}}$ the corresponding subsequence of $(\mathbb{E}_{\mathbb{Q}_{n_k}}[X])_{k \in \mathbb{N}}$ would converge to $\mathbb{E}_{\mathbb{Q}}[X]$. Hence $\mathbb{E}_{\mathbb{Q}}[X]$ is equal to the superior limit of $(\mathbb{E}_{\mathbb{Q}_n}[X])_{n \in \mathbb{N}}$. Similarly, the inferior limit would also be equal to $\mathbb{E}_{\mathbb{Q}}[X]$. This concludes the proof.

Let us now show in several steps that all subsequences of $(\mathbb{Q}_n)_{n \in \mathbb{N}}$ possess a probability measure \mathbb{Q} as a cluster point, and that this measure is a measure solution of the BSDE given by g and ξ . Since $(R_T^n)_{n \in \mathbb{N}}$ (or any subsequence of $(R_T^n)_{n \in \mathbb{N}}$) is bounded in $L^p(\mathbb{P})$, there exists an $R_T \in L^p(\mathbb{P})$ such that $\mathbb{E}[R_T^p] \leq \sup_n \mathbb{E}[(R_T^n)^p]$ together with a subsequence of $(R_T^n)_{n \in \mathbb{N}}$ (or of any subsequence of $(R_T^n)_{n \in \mathbb{N}}$), which we will again denote by $(R_T^n)_{n \in \mathbb{N}}$, converging weakly to R_T , i.e. $\lim_{n \rightarrow \infty} \mathbb{E}[R_T^n X] = \mathbb{E}[R_T X]$ for all $X \in L^q(\mathbb{P})$, where $\frac{1}{q} + \frac{1}{p} = 1$. This holds true since $L^p(\mathbb{P})$ is a reflexive Banach space.

From this we conclude that $\mathbb{E}[R_T X] \geq 0$ for all non-negative and bounded $X \in L^\infty(\mathcal{F}_T)$, which means that R_T is a.s. non-negative (setting $X = \mathbf{1}_{\{R_T < 0\}}$ we have $R_T \mathbf{1}_{\{R_T < 0\}} = 0$ a.s.). Furthermore setting $X = 1$ we get $\mathbb{E}[R_T] = 1$. This means that $\mathbb{Q} := R_T \cdot \mathbb{P}$ is a probability measure.

It remains to show that \mathbb{Q} is indeed a measure solution of the BSDE given by g and ξ and that \mathbb{Q} is uniquely determined and does not depend on the subsequence chosen.

CLAIM1: \mathbb{Q} is equivalent to \mathbb{P} and $\mathbb{E}_{\mathbb{Q}} \left[\left(\frac{d\mathbb{P}}{d\mathbb{Q}} \right)^p \right] < \infty$.

Proof: Using Lemma A.6 we obtain

$$\begin{aligned} \left(\mathbb{E}_{\mathbb{Q}} \left[\left(\frac{1}{R_T} \right)^p \right] \right)^{\frac{1}{p}} &= \sup_{L^\infty(\mathcal{F}_T) \ni X > 0} \frac{\mathbb{E}_{\mathbb{Q}} \left[\frac{1}{R_T} X \right]}{(\mathbb{E}_{\mathbb{Q}} [|X|^q])^{1/q}} = \sup_{L^\infty(\mathcal{F}_T) \ni X > 0} \frac{\mathbb{E}[X]}{(\mathbb{E}[R_T |X|^q])^{1/q}} = \\ &= \sup_{L^\infty(\mathcal{F}_T) \ni X > 0} \lim_{n \rightarrow \infty} \frac{\mathbb{E}[X]}{(\mathbb{E}[R_T^n |X|^q])^{1/q}} \leq \sup_{L^\infty(\mathcal{F}_T) \ni X > 0} \sup_n \frac{\mathbb{E}[X]}{(\mathbb{E}[R_T^n |X|^q])^{1/q}} = \\ &= \sup_n \sup_{L^\infty(\mathcal{F}_T) \ni X > 0} \frac{\mathbb{E}_{\mathbb{Q}_n} \left[\frac{1}{R_T^n} X \right]}{(\mathbb{E}_{\mathbb{Q}_n} [|X|^q])^{1/q}} = \sup_n \left(\mathbb{E}_{\mathbb{Q}_n} \left[\left(\frac{1}{R_T^n} \right)^p \right] \right)^{\frac{1}{p}} < \infty. \end{aligned}$$

This means $\mathbb{E} \left[\frac{1}{R_T^{p-1}} \right] = \mathbb{E} \left[R_T \left(\frac{1}{R_T} \right)^p \right] < \infty$, and therefore $R_T > 0$ \mathbb{P} -a.s., and thus we have $\mathbb{Q} \sim \mathbb{P}$. \square

Now for $n \in \mathbb{N}$ set $R^n := \mathbb{E}[R_T^n | \mathcal{F}]$, write

$$R^n = \exp \left(\int_0^\cdot \zeta_s^n dW_s - \frac{1}{2} \int_0^\cdot |\zeta_s^n|^2 ds \right)$$

for some progressively measurable ζ^n , and similarly

$$R = \exp \left(\int_0^\cdot \zeta_s dW_s - \frac{1}{2} \int_0^\cdot |\zeta_s|^2 ds \right),$$

with $R := \mathbb{E}[R_T | \mathcal{F}]$. We now claim that ζ^n converges to ζ in a weak sense.

CLAIM2:

$$\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T \zeta_s^n \cdot \lambda_s ds \right] = \mathbb{E}_{\mathbb{Q}} \left[\int_0^T \zeta_s \cdot \lambda_s ds \right]$$

for all progressively measurable \mathbb{R}^d -valued λ such that $\mathbb{E} \left[\left(\int_0^T |\lambda_s|^2 ds \right)^{\frac{q}{2}} \right] < \infty$.

Proof: Using Itô's formula we obtain for $n \in \mathbb{N}$

$$R_T^n = 1 + \int_0^T R_s^n \zeta_s^n dW_s \tag{7}$$

and

$$R_T = 1 + \int_0^T R_s \zeta_s dW_s.$$

Now define $X_T := \int_0^T \lambda_s dW_s$ and for $t \in [0, T]$ let $X_t := \int_0^t \lambda_s dW_s$. Then $\mathbb{E}[R_T^n X_T]$ converges to $\mathbb{E}[R_T X_T]$, since $X_T \in L^q(\mathbb{P})$, which follows from the BDG inequalities. On the other hand we can calculate the co-variation of the martingales R^n and X by

$$\langle R^n, X \rangle = \int_0^\cdot R_s^n \zeta_s^n \lambda_s ds.$$

Therefore

$$\mathbb{E}[R_{\tau_k}^n X_{\tau_k}] = \mathbb{E} \left[\int_0^{\tau_k} R_s^n \zeta_s^n \lambda_s ds \right]$$

for some localizing sequence of stopping times (τ_k) .

Using (7), $\sup_n \mathbb{E}[(R_T^n)^p] < \infty$ and the BDG inequalities we have

$$\sup_n \mathbb{E} \left[\left(\int_0^T |R_s^n \zeta_s^n|^2 ds \right)^{\frac{p}{2}} \right] < \infty, \tag{8}$$

which by Cauchy-Schwarz' and Hölder's inequalities implies $\sup_n \mathbb{E} \left[\int_0^T |R_s^n \zeta_s^n \lambda_s| ds \right] < \infty$. By dominated convergence for $k \rightarrow \infty$ this implies for $n \in \mathbb{N}$

$$\mathbb{E}[R_T^n X_T] = \mathbb{E} \left[\int_0^T R_s^n \zeta_s^n \lambda_s ds \right].$$

Here we use in particular that as a corollary of Doob's inequality $\sup_{t \in [0, T]} |R_t^n| \in L^p(\mathbb{P})$ and $\sup_{t \in [0, T]} |X_t| \in L^q(\mathbb{P})$, such that $R_T^n X_T$ is integrable.

Similarly

$$\mathbb{E}[R_T X_T] = \mathbb{E} \left[\int_0^T R_s \zeta_s \lambda_s ds \right].$$

Finally

$$\begin{aligned}\mathbb{E} \left[\int_0^T R_s^n \zeta_s^n \lambda_s \, ds \right] &= \int_0^T \mathbb{E} [R_s^n \zeta_s^n \lambda_s] \, ds = \int_0^T \mathbb{E} \left[\mathbb{E} [R_T^n | \mathcal{F}_s] \zeta_s^n \lambda_s \right] \, ds = \\ &= \int_0^T \mathbb{E} [\mathbb{E} [R_T^n \zeta_s^n \lambda_s | \mathcal{F}_s]] \, ds = \mathbb{E} \left[\int_0^T R_T^n \zeta_s^n \lambda_s \, ds \right] = \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T \zeta_s^n \lambda_s \, ds \right]\end{aligned}$$

And similarly $\mathbb{E} \left[\int_0^T R_s \zeta_s \lambda_s \, ds \right] = \mathbb{E}_{\mathbb{Q}} \left[\int_0^T \zeta_s \lambda_s \, ds \right]$.

Now the assertion follows from the convergence of $\mathbb{E} [R_T^n X_T]$ to $\mathbb{E} [R_T X_T]$ as $n \rightarrow \infty$. \square

It is not difficult to show that for $n \in \mathbb{N}$, $\xi_n \in L^2(\mathbb{Q}_n)$ using Hölder's inequality and *ii*) as well as the p -integrability of R_T^n . The same holds for ξ and \mathbb{Q} . We define $W^{\mathbb{Q}_n} := W - \int_0^\cdot \zeta_s^n \, ds$ and $W^{\mathbb{Q}} := W - \int_0^\cdot \zeta_s \, ds$ which are Brownian motions with respect to \mathbb{Q}_n and \mathbb{Q} respectively. We can furthermore write:

$$\begin{aligned}\xi_n &= \mathbb{E}_{\mathbb{Q}_n} [\xi_n] + \int_0^T Z_s^n \, dW_s^{\mathbb{Q}_n}, \\ \xi &= \mathbb{E}_{\mathbb{Q}} [\xi] + \int_0^T Z_s \, dW_s^{\mathbb{Q}},\end{aligned}$$

with some progressively measurable Z^n and Z .

Now define

$$Y := \mathbb{E}_{\mathbb{Q}} [\xi | \mathcal{F}].$$

In order to complete the proof we have to show $\zeta = g(\cdot, Y, Z)$. This will follow from $\zeta^n = g_n(\cdot, Y^n, Z^n)$, $n \in \mathbb{N}$, using an appropriate kind of convergence of ζ^n to ζ and Z^n to Z . We will use the type of convergence shown in CLAIM2. It has the property of uniqueness of limits, as shown in the following.

If $\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T a_s^n \lambda_s \, ds \right] = \mathbb{E}_{\mathbb{Q}} \left[\int_0^T a_s \lambda_s \, ds \right]$ for all bounded progressively measurable λ and at the same time $\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T a_s^n \lambda_s \, ds \right] = \mathbb{E}_{\mathbb{Q}} \left[\int_0^T b_s \lambda_s \, ds \right]$ for all such λ , then a and b must be equal $d\mathbb{P} \otimes dt$ -a.e.

This follows from $\mathbb{E}_{\mathbb{Q}} \left[\int_0^T (b_s - a_s) \lambda_s \, ds \right] = 0$ for all bounded λ and the equivalence of \mathbb{Q} and \mathbb{P} . We will therefore apply the following strategy.

In order to complete the proof, recalling CLAIM2, it is sufficient to show

$$\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T g_n(s, Y_s^n, Z_s^n) \lambda_s \, ds \right] = \mathbb{E}_{\mathbb{Q}} \left[\int_0^T g(s, Y_s, Z_s) \lambda_s \, ds \right] \quad (9)$$

for a class of progressive λ large enough to be specified later. In order to prove this we will first show

$$\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Z_s^n \lambda_s \, ds \right] = \mathbb{E}_{\mathbb{Q}} \left[\int_0^T Z_s \lambda_s \, ds \right],$$

and then use

$$\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T |Z_s^n|^2 \, ds \right] = \mathbb{E}_{\mathbb{Q}} \left[\int_0^T |Z_s|^2 \, ds \right],$$

to conclude

$$\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T |Z_s^n - Z_s|^2 \, ds \right] = 0,$$

from which

$$\lim_{n \rightarrow \infty} g_n(s, Y_s^n, Z_s^n) = g(s, Y_s, Z_s) \quad \text{a.e.}$$

will follow after passing to a subsequence. This conclusion, obtained in the following six step argument, will finally imply (9).

STEP1: For all bounded progressively measurable processes λ we have:

$$\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Z_s^n \lambda_s ds \right] = \mathbb{E}_{\mathbb{Q}} \left[\int_0^T Z_s \lambda_s ds \right].$$

Proof: For $n \in \mathbb{N}$ first write $\xi_n R_T^n$ as

$$\xi_n R_T^n = \mathbb{E}[\xi_n R_T^n] + \int_0^T \eta_s^n dW_s$$

and define the martingale $V^n := \mathbb{E}[\xi_n R_T^n] + \int_0^\cdot \eta_s^n dW_s = \mathbb{E}[\xi_n R_T^n | \mathcal{F}_\cdot]$. Using $\xi_n = \frac{V_T^n}{R_T^n}$ and remembering $R_T^n = 1 + \int_0^T R_s^n \zeta_s^n dW_s$ we can use Itô's formula to express Z^n in terms of R^n , V^n , ζ^n and η^n explicitly (e.g. Lemma 1.6.7 in [16]). We end up with

$$Z^n = \frac{\eta^n - V^n \zeta^n}{R^n}, \quad n \in \mathbb{N}.$$

A similar formula holds for Z , ζ , R , $V := \mathbb{E}[R_T \xi | \mathcal{F}_\cdot]$ and η such that $\xi R_T = \mathbb{E}[\xi R_T] + \int_0^T \eta_s dW_s$. Now let λ be as in the claim. Then for $n \in \mathbb{N}$

$$\mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Z_s^n \lambda_s ds \right] = \mathbb{E} \left[\int_0^T (\eta_s^n - V_s^n \zeta_s^n) \lambda_s ds \right].$$

We first want to show $\lim_{n \rightarrow \infty} \mathbb{E} \left[\int_0^T \eta_s^n \lambda_s ds \right] = \mathbb{E} \left[\int_0^T \eta_s \lambda_s ds \right]$. The argument relies on the fact that $\lim_{n \rightarrow \infty} \mathbb{E}[\xi_n R_T^n X] = \mathbb{E}[\xi R_T X]$ for $X := \int_0^T \lambda_s dW_s$, on the equation

$$\mathbb{E} \left[\int_0^T \eta_s^n \lambda_s ds \right] = \mathbb{E} \left[\left(\int_0^T \eta_s^n dW_s \right) \left(\int_0^T \lambda_s dW_s \right) \right] = \mathbb{E}[\xi_n R_T^n X]$$

valid for $n \in \mathbb{N}$ and a similar one for the limiting processes. This is guaranteed by $\xi_n R_T^n$ being in some $L^{p'}(\mathbb{P})$ with $1 < p'$ small enough following from Hölder's inequality and *i), ii)*, which also implies $\mathbb{E} \left[\left(\int_0^T |\eta_s^n|^2 ds \right)^{p'/2} \right] < \infty$.

The next argument gives $\lim_{n \rightarrow \infty} \mathbb{E}[\xi_n R_T^n X] = \mathbb{E}[\xi R_T X]$. In fact,

$$\begin{aligned} |\mathbb{E}[\xi_n R_T^n X] - \mathbb{E}[\xi R_T X]| &\leq |\mathbb{E}[\xi_n R_T^n X] - \mathbb{E}[\xi R_T^n X]| + |\mathbb{E}[\xi R_T^n X] - \mathbb{E}[\xi R_T X]| \leq \\ &\leq \mathbb{E}[|\xi_n X - \xi X|^q]^{\frac{1}{q}} \sup_n \mathbb{E}[(R_T^n)^p]^{\frac{1}{p}} + |\mathbb{E}[\xi R_T^n X] - \mathbb{E}[\xi R_T X]| \leq \\ &\leq \mathbb{E}[|\xi_n - \xi|^{2q}]^{\frac{1}{2q}} \mathbb{E}[|X|^{2q}]^{\frac{1}{2q}} \sup_n \mathbb{E}[(R_T^n)^p]^{\frac{1}{p}} + |\mathbb{E}[R_T^n \xi X] - \mathbb{E}[R_T \xi X]| \longrightarrow 0 \end{aligned} \quad (10)$$

for $n \rightarrow \infty$. Here we employed the convergence of ξ_n to ξ in $L^{2q}(\mathbb{P})$ as well as $X \in L^r(\mathbb{P})$ for all $r \geq 1$. Furthermore we used the weak convergence of R_T^n to R_T and $\xi X \in L^q(\mathbb{P})$.

Secondly we have to show $\lim_{n \rightarrow \infty} \mathbb{E} \left[\int_0^T V_s^n \zeta_s^n \lambda_s ds \right] = \mathbb{E} \left[\int_0^T V_s \zeta_s \lambda_s ds \right]$.

Applying Bayes' formula for $n \in \mathbb{N}$ we have $Y^n = \frac{\mathbb{E}[R_T^n \xi_n | \mathcal{F}_\cdot]}{R^n}$ and thus

$$\mathbb{E} \left[\int_0^T V_s^n \zeta_s^n \lambda_s ds \right] = \mathbb{E} \left[\int_0^T \mathbb{E}[R_T^n \xi_n | \mathcal{F}_s] \zeta_s^n \lambda_s ds \right] = \mathbb{E} \left[\int_0^T Y_s^n R_s^n \zeta_s^n \lambda_s ds \right] =$$

$$= \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Y_s^n \zeta_s^n \lambda_s \, ds \right].$$

An analogous equation holds for the limiting processes. We now proceed in two steps: First we show that the difference between $\mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Y_s^n \zeta_s^n \lambda_s \, ds \right]$ and $\mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Y_s \zeta_s^n \lambda_s \, ds \right] = \mathbb{E} \left[\int_0^T Y_s R_s^n \zeta_s^n \lambda_s \, ds \right]$ converges to zero and then we show that $\mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Y_s \zeta_s^n \lambda_s \, ds \right]$ converges to $\mathbb{E}_{\mathbb{Q}} \left[\int_0^T Y_s \zeta_s \lambda_s \, ds \right]$. Using Cauchy-Schwarz' and Hölder's inequalities, as well as

$$\sup_n \mathbb{E} \left[\left(\int_0^T |R_s^n \zeta_s^n \lambda_s|^2 \, ds \right)^{\frac{p}{2}} \right] < \infty$$

(see (8)), the first step would follow from

$$\lim_{n \rightarrow \infty} \mathbb{E} \left[\left(\int_0^T |Y_s^n - Y_s|^2 \, ds \right)^{\frac{q}{2}} \right] = 0.$$

This holds essentially because of condition *iii*), according to which Y^n has a limit in the above sense. It remains to verify that $Y = \tilde{Y}$. For this purpose it will be sufficient to show that Y^n converges both to Y and \tilde{Y} in a weak sense. Setting $X = \int_0^T \mu_s \, ds$ for some bounded progressively measurable μ we have

$$\begin{aligned} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Y_s^n \mu_s \, ds \right] &= \mathbb{E} \left[\int_0^T \mathbb{E}[R_T^n \xi_n | \mathcal{F}_s] \mu_s \, ds \right] = \mathbb{E} \left[R_T^n \xi_n \int_0^T \mu_s \, ds \right] = \mathbb{E}[R_T^n \xi_n X] \longrightarrow \\ &\longrightarrow \mathbb{E}[R_T \xi X] = \dots = \mathbb{E}_{\mathbb{Q}} \left[\int_0^T Y_s \mu_s \, ds \right] \text{ as } n \rightarrow \infty. \end{aligned}$$

For the limit we used the reasoning of (10).

On the other hand Y^n must converge to \tilde{Y} in the same sense. Indeed we have for $n \in \mathbb{N}$

$$\begin{aligned} \left| \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Y_s^n \mu_s \, ds \right] - \mathbb{E}_{\mathbb{Q}} \left[\int_0^T \tilde{Y}_s \mu_s \, ds \right] \right| &= \left| \mathbb{E} \left[R_T^n \int_0^T Y_s^n \mu_s \, ds \right] - \mathbb{E} \left[R_T \int_0^T \tilde{Y}_s \mu_s \, ds \right] \right| \leq \\ &\leq \left| \mathbb{E} \left[R_T^n \int_0^T (Y_s^n - \tilde{Y}_s) \mu_s \, ds \right] \right| + \left| \mathbb{E} \left[R_T \int_0^T \tilde{Y}_s \mu_s \, ds \right] - \mathbb{E} \left[R_T^n \int_0^T \tilde{Y}_s \mu_s \, ds \right] \right| \leq \\ &\leq \sup_n \mathbb{E} [(R_T^n)^p]^{\frac{1}{p}} \left(\mathbb{E} \left[\left(\int_0^T (Y_s^n - \tilde{Y}_s)^2 \, ds \right)^{\frac{q}{2}} \left(\int_0^T |\mu_s|^2 \, ds \right)^{\frac{q}{2}} \right] \right)^{\frac{1}{q}} + \\ &\quad + \left| \mathbb{E} \left[R_T \int_0^T \tilde{Y}_s \mu_s \, ds \right] - \mathbb{E} \left[R_T^n \int_0^T \tilde{Y}_s \mu_s \, ds \right] \right| \end{aligned}$$

This first summand converges to zero by *i*), *iii*) and the boundedness of μ . The second one converges to zero as well due to the weak convergence of R_T^n to R_T , for which we need $\mathbb{E} \left[\left(\int_0^T |\tilde{Y}_s|^2 \, ds \right)^{\frac{q}{2}} \right] < \infty$.

Therefore Y and \tilde{Y} must coincide owing to uniqueness of weak limits. Thus we have shown that the difference between $\mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Y_s^n \zeta_s^n \lambda_s \, ds \right]$ and $\mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Y_s \zeta_s^n \lambda_s \, ds \right]$ converges to zero.

It remains to note that the difference between $\mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Y_s \zeta_s^n \lambda_s \, ds \right]$ and $\mathbb{E}_{\mathbb{Q}} \left[\int_0^T Y_s \zeta_s \lambda_s \, ds \right]$ tends to zero as well. This is a consequence of CLAIM2.

Here we used $\mathbb{E} \left[\left(\int_0^T |Y_s|^2 ds \right)^{\frac{q}{2}} \right] = \mathbb{E} \left[\left(\int_0^T |\tilde{Y}_s|^2 ds \right)^{\frac{q}{2}} \right] < \infty$. \square

STEP2: We have

$$\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T |Z_s^n|^2 ds \right] = \mathbb{E}_{\mathbb{Q}} \left[\int_0^T |Z_s|^2 ds \right].$$

Proof: This follows from Itô's isometry based on $\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n}[\xi_n] = \mathbb{E}_{\mathbb{Q}}[\xi]$ and $\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n}[\xi_n^2] = \mathbb{E}_{\mathbb{Q}}[\xi^2]$. Both statements follow from the strong convergence of ξ_n to ξ stated in *ii*) and the weak convergence of R_T^n to R_T . We only give details for the last one. In fact

$$\begin{aligned} |\mathbb{E}_{\mathbb{Q}_n}[\xi_n^2] - \mathbb{E}_{\mathbb{Q}}[\xi^2]| &= |\mathbb{E}[R_T^n \xi_n^2] - \mathbb{E}[R_T \xi^2]| + |\mathbb{E}[R_T^n \xi^2] - \mathbb{E}[R_T \xi^2]| \leq \\ &\leq \mathbb{E}[|\xi_n^2 - \xi^2|^q]^{\frac{1}{q}} \sup_n \mathbb{E}[(R_T^n)^p]^{\frac{1}{p}} + |\mathbb{E}[R_T^n \xi^2] - \mathbb{E}[R_T \xi^2]| \leq \\ &\leq \mathbb{E}[|\xi_n + \xi|^{2q}]^{\frac{1}{2q}} \mathbb{E}[|\xi_n - \xi|^{2q}]^{\frac{1}{2q}} \sup_n \mathbb{E}[(R_T^n)^p]^{\frac{1}{p}} + |\mathbb{E}[R_T^n \xi^2] - \mathbb{E}[R_T \xi^2]| \longrightarrow 0 \end{aligned}$$

as $n \rightarrow \infty$. Here we used *ii*), $\sup_n \mathbb{E}[|\xi_n|^{2q}] < \infty$ and $\xi^2 \in L^q(\mathbb{P})$.

STEP3: We claim that, eventually passing to a subsequence, we can assume w.l.o.g.

$$\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T |Z_s^n - Z_s|^2 ds \right] = 0.$$

Proof: First of all, as a consequence of the BDG inequalities, *ii*) and the definition of Z we get $\mathbb{E}_{\mathbb{Q}} \left[\left(\int_0^T |Z_s|^2 ds \right)^{q^2} \right] < \infty$. Moreover, $\mathbb{E}_{\mathbb{Q}}[(1/R_T)^p] < \infty$ combined with Hölder's inequality implies

$$\mathbb{E} \left[\left(\int_0^T |Z_s|^2 ds \right)^q \right] = \mathbb{E}_{\mathbb{Q}} \left[\frac{1}{R_T} \left(\int_0^T |Z_s|^2 ds \right)^q \right] < \infty \quad (11)$$

which in turn implies

$$\sup_n \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T |Z_s|^2 ds \right] < \infty,$$

again by Hölder's inequality.

Using $|Z_s^n - Z_s|^2 = |Z_s^n|^2 - 2Z_s^n Z_s + |Z_s|^2$ and STEP2, we see that it is sufficient to show

$$\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T 2Z_s^n Z_s ds \right] = \mathbb{E}_{\mathbb{Q}} \left[\int_0^T 2Z_s Z_s ds \right]$$

which obviously must follow from an extension of STEP1. The difficulty we have to overcome here is that Z is not necessarily bounded. However by replacing Z with some $\tilde{Z}^k := ((-k) \vee Z) \wedge k$ we have for any $k \in \mathbb{N}$

$$\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Z_s^n \tilde{Z}_s^k ds \right] = \mathbb{E}_{\mathbb{Q}} \left[\int_0^T Z_s \tilde{Z}_s^k ds \right].$$

Since $\lim_{k \rightarrow \infty} \mathbb{E}_{\mathbb{Q}} \left[\int_0^T Z_s \tilde{Z}_s^k ds \right] = \mathbb{E}_{\mathbb{Q}} \left[\int_0^T |Z_s|^2 ds \right]$ using dominated convergence it remains to show

$$\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Z_s^n Z_s ds \right] = \lim_{k \rightarrow \infty} \lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Z_s^n \tilde{Z}_s^k ds \right].$$

Since by Cauchy-Schwarz' inequality $\mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Z_s^n Z_s ds \right], n \in \mathbb{N}$, is a bounded sequence, we can assume w.l.o.g. that it is convergent, after eventually passing to a subsequence. Hence

$$\begin{aligned} & \lim_{k \rightarrow \infty} \lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Z_s^n \tilde{Z}_s^k ds \right] = \\ & = \lim_{k \rightarrow \infty} \lim_{n \rightarrow \infty} \left(\mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Z_s^n (\tilde{Z}_s^k - Z_s) ds \right] + \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Z_s^n Z_s ds \right] \right). \end{aligned}$$

Therefore it remains to show

$$\lim_{k \rightarrow \infty} \lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Z_s^n (\tilde{Z}_s^k - Z_s) ds \right] = 0.$$

We have

$$\begin{aligned} & \sup_n \left| \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T Z_s^n (\tilde{Z}_s^k - Z_s) ds \right] \right|^2 \leq \sup_n \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T |Z_s^n|^2 ds \right] \sup_n \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T |\tilde{Z}_s^k - Z_s|^2 ds \right] \leq \\ & \leq \sup_n \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T |Z_s^n|^2 ds \right] \sup_n \mathbb{E}[(R_T^n)^p]^{\frac{1}{p}} \left(\mathbb{E} \left[\left(\int_0^T |\tilde{Z}_s^k - Z_s|^2 ds \right)^q \right] \right)^{\frac{1}{q}}. \end{aligned}$$

The result follows from $\tilde{Z}^k \rightarrow Z$, dominated convergence and (11). \square

STEP4: Passing to a subsequence once more, we deduce

$$\lim_{n \rightarrow \infty} g_n(\cdot, Y^n, Z^n) = g(\cdot, Y, Z) \quad d\mathbb{P} \otimes ds \text{ a.e.}$$

Proof: We have

$$\begin{aligned} & \mathbb{E} \left[\int_0^T |Z_s^n - Z_s|^2 \wedge \frac{1}{T} ds \right] = \mathbb{E}_{\mathbb{Q}_n} \left[\frac{1}{R_T^n} \int_0^T |Z_s^n - Z_s|^2 \wedge \frac{1}{T} ds \right] \leq \\ & \leq \left(\sup_n \mathbb{E}_{\mathbb{Q}_n} \left[\left(\frac{1}{R_T^n} \right)^p \right] \right)^{\frac{1}{p}} \left(\mathbb{E}_{\mathbb{Q}_n} \left[\left(\int_0^T |Z_s^n - Z_s|^2 \wedge \frac{1}{T} ds \right)^q \right] \right)^{\frac{1}{q}} \leq \\ & \leq \left(\sup_n \mathbb{E}_{\mathbb{Q}_n} \left[\left(\frac{1}{R_T^n} \right)^p \right] \right)^{\frac{1}{p}} \left(\mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T |Z_s^n - Z_s|^2 ds \right] \right)^{\frac{1}{q}} \rightarrow 0 \text{ as } n \rightarrow \infty. \end{aligned}$$

Hence by choosing a subsequence which we again denote by the same symbols we have $|Z^n - Z|^2 \wedge \frac{1}{T} \rightarrow 0$ a.e., which means $Z^n \rightarrow Z$ a.e. We can also assume $Y^n \rightarrow Y = \tilde{Y}$ a.e. This means in particular that $(Y_s^n(\omega), Z_s^n(\omega))$ is a bounded sequence for a.a. (ω, s) . Hence by *iv*)

$$\lim_{n \rightarrow \infty} |g_n(\omega, s, Y_s^n(\omega), Z_s^n(\omega)) - g(\omega, s, Y_s(\omega), Z_s(\omega))| = 0$$

for a.a. (ω, s) . We also have using the continuity of g

$$\lim_{n \rightarrow \infty} |g(\omega, s, Y_s^n(\omega), Z_s^n(\omega)) - g(\omega, s, Y_s(\omega), Z_s(\omega))| = 0$$

for a.a. (ω, s) . This proves the assertion. \square

STEP5: For all bounded progressively measurable λ such that $\sup_n |g_n(s, Y_s^n, Z_s^n)\lambda_s| \leq C_\lambda$ with some constant $C_\lambda \in \mathbb{R}$ depending only on λ we have:

$$\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T g_n(s, Y_s^n, Z_s^n) \lambda_s \, ds \right] = \mathbb{E}_{\mathbb{Q}} \left[\int_0^T g(s, Y_s, Z_s) \lambda_s \, ds \right].$$

Proof: Since $\mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T g(s, Y_s, Z_s) \lambda_s \, ds \right]$ converges to $\mathbb{E}_{\mathbb{Q}} \left[\int_0^T g(s, Y_s, Z_s) \lambda_s \, ds \right]$ according to the weak convergence of R_T^n to R_T and the boundedness of $|g(s, Y_s, Z_s)\lambda_s|$, it is enough to show

$$\mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T g_n(s, Y_s^n, Z_s^n) \lambda_s \, ds \right] - \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T g(s, Y_s, Z_s) \lambda_s \, ds \right] \rightarrow 0.$$

But this follows from STEP4 by noting

$$\begin{aligned} & \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T (g_n(s, Y_s^n, Z_s^n) - g(s, Y_s, Z_s)) \lambda_s \, ds \right] \leq \\ & \leq \sup_n \mathbb{E}[(R_T^n)^p]^{\frac{1}{p}} \left(\mathbb{E} \left[\left(\int_0^T (g_n(s, Y_s^n, Z_s^n) - g(s, Y_s, Z_s)) \lambda_s \, ds \right)^q \right] \right)^{\frac{1}{q}} \end{aligned}$$

which tends to zero for $n \rightarrow \infty$ by dominated convergence using the uniform boundedness of $g_n(\cdot, Y^n, Z^n)\lambda$ and hence $g(\cdot, Y, Z)\lambda$. \square

STEP6: Using CLAIM2, STEP5 and $\zeta^n = g_n(\cdot, Y^n, Z^n)$, $n \in \mathbb{N}$, we have

$$\mathbb{E}_{\mathbb{Q}} \left[\int_0^T (\zeta_s - g(s, Y_s, Z_s)) \lambda_s \, ds \right] = 0$$

for all bounded progressive λ such that $\sup_n |g_n(\cdot, Y^n, Z^n)\lambda| \leq C_\lambda$. Now define for all $C > 0$

$$\lambda^C := (\zeta - g(\cdot, Y, Z)) \mathbf{1}_{\{|\zeta - g(\cdot, Y, Z)| \leq C\}} \mathbf{1}_{\{\sup_n |g_n(\cdot, Y^n, Z^n)| \leq C\}}$$

which is progressive, bounded and satisfies $|g_n(\cdot, Y^n, Z^n)\lambda^C| \leq C^2$. This implies

$$\mathbb{E}_{\mathbb{Q}} \left[\int_0^T |\zeta_s - g(s, Y_s, Z_s)|^2 \mathbf{1}_{\{|\zeta_s - g(s, Y_s, Z_s)| \leq C\}} \mathbf{1}_{\{\sup_n |g_n(s, Y_s^n, Z_s^n)| \leq C\}} \, ds \right] = 0,$$

and hence

$$|\zeta - g(\cdot, Y, Z)|^2 \mathbf{1}_{\{|\zeta - g(\cdot, Y, Z)| \leq C\}} \mathbf{1}_{\{\sup_n |g_n(\cdot, Y^n, Z^n)| \leq C\}} = 0 \quad d\mathbb{P} \otimes dt - \text{ a.e.}$$

Clearly $\sup_n |g_n(\omega, s, Y_s^n(\omega), Z_s^n(\omega))|$, $g(\omega, s, Y_s(\omega), Z_s(\omega))$ and $\zeta_s(\omega)$ are real numbers for almost all (ω, s) . Hence letting C go to infinity we have $\zeta = g(\cdot, Y, Z)$ $d\mathbb{P} \otimes ds$ -a.e., which means that \mathbb{Q} is a measure solution of the BSDE given by g and ξ .

It remains to mention that although in our construction \mathbb{Q} depends on the choice of a weakly convergent subsequence of $(R_T^n)_{n \in \mathbb{N}}$, we always end up with the same \mathbb{Q} , since it is already determined by $\tilde{Y} = Y = \mathbb{E}_{\mathbb{Q}}[\xi | \mathcal{F}]$. Once the Y -process of a measure solution \mathbb{Q} is given, the Z -process is uniquely determined by the martingale part of Y and this already determines $\mathbb{Q} = \mathcal{E}(g(\cdot, Y, Z) \bullet W)_T \cdot \mathbb{P}$. \square

Remark 2.1. *In particular we have shown*

$$\mathbb{E} \left[\left(\frac{d\mathbb{Q}}{d\mathbb{P}} \right)^p \right] \leq \sup_n \mathbb{E} \left[\left(\frac{d\mathbb{Q}_n}{d\mathbb{P}} \right)^p \right], \quad \mathbb{E}_{\mathbb{Q}} \left[\left(\frac{d\mathbb{P}}{d\mathbb{Q}} \right)^p \right] \leq \sup_n \mathbb{E}_{\mathbb{Q}_n} \left[\left(\frac{d\mathbb{P}}{d\mathbb{Q}_n} \right)^p \right].$$

Remark 2.2. We have also shown $\tilde{Y} = \mathbb{E}_{\mathbb{Q}}[\xi|\mathcal{F}]$ $d\mathbb{P} \otimes dt$ -a.e.

Remark 2.3. In addition we have proven that each subsequence of $(Z^n)_{n \in \mathbb{N}}$ has a subsequence which converges to Z $\mathbb{P} \otimes \lambda_{[0,T]}$ -a.e. In other words $(Z^n)_{n \in \mathbb{N}}$ converges to Z in measure.

In the following theorem, the result of Theorem 2.1 will be refined and extended to a situation in which the generating sequence $(g_n)_{n \in \mathbb{N}}$ converges to g only uniformly on compacts avoiding the origin in \mathbb{R}^d and in which accordingly only a.-measure solutions are involved.

Theorem 2.2. Let $(\mathbb{Q}_n)_{n \in \mathbb{N}}$ be a sequence of measures, each giving an a.-measure solution of the BSDE given by some g_n and ξ_n . Let $p, q > 1$ such that $1/p + 1/q = 1$ and such that:

i)

$$\sup_n \mathbb{E} \left[\left(\frac{d\mathbb{Q}_n}{d\mathbb{P}} \right)^p \right] < \infty, \quad \sup_n \mathbb{E}_{\mathbb{Q}_n} \left[\left(\frac{d\mathbb{P}}{d\mathbb{Q}_n} \right)^p \right] < \infty,$$

ii) $\xi_n \rightarrow \xi$ as $n \rightarrow \infty$ in $L^{2q}(\mathbb{P})$ and $\xi \in L^{q^2}(\mathbb{P})$,

iii) $Y^n := \mathbb{E}_{\mathbb{Q}_n}[\xi_n|\mathcal{F}]$ converges for $n \rightarrow \infty$ to some $\tilde{Y} \in \mathcal{H}^q(\mathbb{R}, \mathbb{P})$ a.e. and in $\mathcal{H}^q(\mathbb{R}, \mathbb{P})$,

iv) for a.a. (ω, s) : $\lim_{n \rightarrow \infty} g_n(\omega, s, \cdot, \cdot) = g(\omega, s, \cdot, \cdot)$ (with a proper g) uniformly on compacts K such that $\{(y, z) | y \in \mathbb{R}, z = 0 \in \mathbb{R}^d\} \cap K = \emptyset$. Let furthermore $g(\omega, s, \cdot, \cdot)$ be continuous outside $\{(y, z) | y \in \mathbb{R}, z = 0 \in \mathbb{R}^d\}$ for a.a. (ω, s) .

Then there exists an a.-measure solution of the BSDE given by g and ξ .

Proof. The proof is very similar to the proof of Theorem 2.1. We again start by passing to a subsequence in order to obtain a weak cluster point. The proof differs beginning with STEP4, since $\lim_{n \rightarrow \infty} g_n(\cdot, Y^n, Z^n) = g(\cdot, Y, Z)$ will not hold in general. Instead we can show

$$\lim_{n \rightarrow \infty} g_n(\cdot, Y^n, Z^n) \mathbf{1}_{\{Z^n \neq 0\}} \mathbf{1}_{\{Z \neq 0\}} = g(\cdot, Y, Z) \mathbf{1}_{\{Z \neq 0\}} \quad d\mathbb{P} \otimes dt - \text{ a.e.}$$

For this purpose, using STEP2 (see STEP4 in the proof of Theorem 2.1 for details), we can assume w.l.o.g. that $Z^n \rightarrow Z$ a.e. Hence the sequence $(Z_s^n(\omega))$ will for a.a. (ω, s) such that $Z_s(\omega) \neq 0$ be contained in some compact set not containing 0 for n large enough. Therefore

$$\lim_{n \rightarrow \infty} |g_n(s, Y_s^n, Z_s^n)(\omega) \mathbf{1}_{\{Z_s^n \neq 0\}}(\omega) \mathbf{1}_{\{Z_s \neq 0\}}(\omega) - g(s, Y_s^n, Z_s^n)(\omega) \mathbf{1}_{\{Z_s^n \neq 0\}}(\omega) \mathbf{1}_{\{Z_s \neq 0\}}(\omega)| = 0$$

for a.a. (ω, s) . We also have, by the continuity of g outside $\{(y, z) | y \in \mathbb{R}, z = 0\}$:

$$\lim_{n \rightarrow \infty} |g(\omega, s, Y_s^n(\omega), Z_s^n(\omega)) \mathbf{1}_{\{Z_s^n \neq 0\}}(\omega) \mathbf{1}_{\{Z_s \neq 0\}}(\omega) - g(\omega, s, Y_s(\omega), Z_s(\omega)) \mathbf{1}_{\{Z_s \neq 0\}}(\omega)| = 0$$

for a.a. (ω, s) . This proves the assertion.

Using this we can replace STEP5 in the proof of Theorem 2.1 by the statement

$$\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T g_n(s, Y_s^n, Z_s^n) \mathbf{1}_{\{Z_s^n \neq 0\}} \mathbf{1}_{\{Z_s \neq 0\}} \lambda_s ds \right] = \mathbb{E}_{\mathbb{Q}} \left[\int_0^T g(s, Y_s, Z_s) \mathbf{1}_{\{Z_s \neq 0\}} \lambda_s ds \right]$$

for all bounded progressively measurable λ such that $\sup_n |g_n(\cdot, Y^n, Z^n) \mathbf{1}_{\{Z^n \neq 0\}} \mathbf{1}_{\{Z \neq 0\}} \lambda| \leq C_\lambda$ a.e. with some constant $C_\lambda > 0$ depending only on λ .

On the other hand, using CLAIM2, we have

$$\lim_{n \rightarrow \infty} \mathbb{E}_{\mathbb{Q}_n} \left[\int_0^T \zeta_s^n \mathbf{1}_{\{\inf_{m \geq N} |Z_s^m| > 0\}} \mathbf{1}_{\{Z_s \neq 0\}} \lambda_s ds \right] = \mathbb{E}_{\mathbb{Q}} \left[\int_0^T \zeta_s \mathbf{1}_{\{\inf_{m \geq N} |Z_s^m| > 0\}} \mathbf{1}_{\{Z_s \neq 0\}} \lambda_s ds \right]$$

for all progressive bounded λ and all $N \in \mathbb{N}$. Considering

$$g_n(\cdot, Y^n, Z^n) \mathbf{1}_{\{Z^n \neq 0\}} \mathbf{1}_{\{\inf_{m \geq N} |Z^m| > 0\}} = \zeta^n \mathbf{1}_{\{Z^n \neq 0\}} \mathbf{1}_{\{\inf_{m \geq N} |Z^m| > 0\}} = \zeta^n \mathbf{1}_{\{\inf_{m \geq N} |Z^m| > 0\}}$$

for all $n \geq N$, this implies

$$\mathbb{E}_{\mathbb{Q}} \left[\int_0^T (\zeta_s \mathbf{1}_{\{\inf_{m \geq N} |Z_s^m| > 0\}} \mathbf{1}_{\{Z_s \neq 0\}} - g(s, Y_s, Z_s) \mathbf{1}_{\{\inf_{m \geq N} |Z_s^m| > 0\}} \mathbf{1}_{\{Z_s \neq 0\}}) \lambda_s \, ds \right] = 0 \quad (12)$$

for all bounded λ such that $\sup_n |g_n(\cdot, Y^n, Z^n) \mathbf{1}_{\{Z^n \neq 0\}} \mathbf{1}_{\{Z \neq 0\}} \lambda| \leq C\lambda$. Now define $C > 0$

$$\lambda^C := (\zeta - g(\cdot, Y, Z)) \mathbf{1}_{\{|\zeta - g(\cdot, Y, Z)| \leq C\}} \mathbf{1}_{\{\sup_n |g_n(\cdot, Y^n, Z^n) \mathbf{1}_{\{Z^n \neq 0\}} \mathbf{1}_{\{Z \neq 0\}}| \leq C\}}$$

which is progressive, bounded and satisfies $|g_n(\cdot, Y^n, Z^n) \mathbf{1}_{\{Z^n \neq 0\}} \mathbf{1}_{\{Z \neq 0\}} \lambda^C| \leq C^2$. Inserting this into (12) yields

$$\begin{aligned} & |\zeta - g(\cdot, Y, Z)| \mathbf{1}_{\{Z \neq 0\}} \mathbf{1}_{\{\inf_{m \geq N} |Z^m| > 0\}} \mathbf{1}_{\{|\zeta - g(\cdot, Y, Z)| \leq C\}} \\ & \cdot \mathbf{1}_{\{\sup_n |g_n(\cdot, Y^n, Z^n) \mathbf{1}_{\{Z^n \neq 0\}} \mathbf{1}_{\{Z \neq 0\}}| \leq C\}} = 0. \end{aligned}$$

If we let $C, N \rightarrow \infty$, we finally obtain

$$\zeta \mathbf{1}_{\{Z \neq 0\}} = g(\cdot, Y, Z) \mathbf{1}_{\{Z \neq 0\}} \quad d\mathbb{P} \otimes dt \text{ a.e.}$$

taking into account that $Z_s(\omega) \neq 0$ implies that $Z_s^n(\omega)$ will lie in a compact set not containing 0 for n large enough for a.a. (ω, s) and then $g_n(s, Y_s^n, Z_s^n)(\omega)$ will be bounded and the sequence $(Z_s^n(\omega))$ will be bounded away from 0.

We have thus proven that $\mathbb{Q} = \mathcal{E}(\zeta \bullet W)_T \cdot \mathbb{P}$ is an a.-measure solution. \square

Remark 2.4. *As in Theorem 2.1 it follows that*

$$\mathbb{E} \left[\left(\frac{d\mathbb{Q}}{d\mathbb{P}} \right)^p \right] \leq \sup_n \mathbb{E} \left[\left(\frac{d\mathbb{Q}_n}{d\mathbb{P}} \right)^p \right], \quad \mathbb{E}_{\mathbb{Q}} \left[\left(\frac{d\mathbb{P}}{d\mathbb{Q}} \right)^p \right] \leq \sup_n \mathbb{E}_{\mathbb{Q}_n} \left[\left(\frac{d\mathbb{P}}{d\mathbb{Q}_n} \right)^p \right].$$

Remark 2.5. *We have also shown $\tilde{Y} = \mathbb{E}_{\mathbb{Q}}[\xi | \mathcal{F}] \, d\mathbb{P} \otimes dt$ -a.e.*

Remark 2.6. *In addition we have proven that each subsequence of $(Z_n)_{n \in \mathbb{N}}$ has a subsequence which converges to Z , $d\mathbb{P} \otimes dt$ -a.e. (where Z is already uniquely determined by the martingale part of \tilde{Y}). In other words $(Z_n)_{n \in \mathbb{N}}$ converges to Z in measure.*

3 Existence Results

Equipped with the stability properties of the preceding section, we can now return to the question of existence of measure solutions, and thus to solutions of the associated BSDE. Using regularization techniques we will derive existence results in scenarios where the generator function g is continuous off the origin in \mathbb{R}^d and roughly of at most linear growth in z , i.e. the classical generator $f(\cdot, y, z) = z \cdot g(\cdot, y, z)$, $y \in \mathbb{R}$, $z \in \mathbb{R}^d$ is subquadratic in z . We will therefore consider proper functions

$$g : \Omega \times [0, T] \times \mathbb{R} \times \mathbb{R}^d \rightarrow \mathbb{R}^d$$

and $f(\cdot, y, z) = z \cdot g(\cdot, y, z)$, $y \in \mathbb{R}$, $z \in \mathbb{R}^d$.

Lemma 3.1. *Let $\xi \in L^\infty(\mathcal{F}_T)$ and let g be proper such that*

- i) g and f are both bounded by some constant M ,
- ii) $g(\omega, s, \cdot)$ is continuous at all points (y, z) such that $z \neq 0$ for a.a. (ω, s) ,
- iii) $f(\omega, s, \cdot)$ is uniformly continuous for a.a. (ω, s) .

Then there exists a measure solution of the BSDE given by g and ξ .

Proof. STEP1 We regularize the generator. To do this, for $\varepsilon > 0, y \in \mathbb{R}, z \in \mathbb{R}^d$ let

$$\tilde{g}_\varepsilon(\cdot, y, z) := \int_{\mathbb{R} \times \mathbb{R}^d} g(\cdot, y - \hat{y}, z - \hat{z}) \rho_\varepsilon(\hat{y}, \hat{z}) d(\hat{y}, \hat{z}) = g * \rho_\varepsilon(\cdot, y, z)$$

with

$$\rho_\varepsilon(\hat{y}, \hat{z}) := \frac{1}{(2\pi\varepsilon)^{\frac{d+1}{2}}} \exp\left(-\frac{1}{2\varepsilon} (|\hat{y}|^2 + |\hat{z}|^2)\right)$$

Now define for $y \in \mathbb{R}$ and $z \in \mathbb{R}^d$

$$\tilde{f}_\varepsilon(\cdot, y, z) := z \tilde{g}_\varepsilon(\cdot, y, z).$$

We claim that $\lim_{\varepsilon \rightarrow 0} \tilde{f}_\varepsilon(\omega, s, \cdot, \cdot) = f$ uniformly for almost all fixed (ω, s) . Indeed, since $f(\omega, s, \cdot, \cdot)$ is uniformly continuous and bounded, $\lim_{\varepsilon \rightarrow 0} (f * \rho_\varepsilon)(\omega, s, \cdot, \cdot) = f(\omega, s, \cdot, \cdot)$ uniformly and

$$|f * \rho_\varepsilon(\cdot, y, z) - z \tilde{g}_\varepsilon(\cdot, y, z)| \leq M \int_{\mathbb{R} \times \mathbb{R}^d} |\hat{z}| \rho_\varepsilon(\hat{y}, \hat{z}) d(\hat{y}, \hat{z}) \rightarrow 0 \text{ as } \varepsilon \rightarrow 0.$$

Hence $\lim_{\varepsilon \rightarrow 0} \tilde{f}_\varepsilon(\omega, s, \cdot, \cdot) = f(\omega, s, \cdot, \cdot)$ uniformly as well.

STEP2 We now construct Lipschitz continuous and uniformly bounded approximating sequences $(g_n)_{n \in \mathbb{N}}$ resp. $(f_n)_{n \in \mathbb{N}}$ of g resp. f . To this end, for any $\varepsilon > 0, s \in [0, T], y \in \mathbb{R}, z \in \mathbb{R}^d$ let

$$\delta_s^{(\varepsilon)}(\omega) := \sup_{y, z} |\tilde{f}_\varepsilon(\omega, s, y, z) - f(\omega, s, y, z)|.$$

We have $\lim_{\varepsilon \rightarrow 0} \delta_s^{(\varepsilon)}(\omega) = 0$ for a.a. (ω, s) and, by dominated convergence, we also have $\lim_{\varepsilon \rightarrow 0} \mathbb{E} \left[\int_0^T \left(\delta_s^{(\varepsilon)} \right)^4 ds \right] = 0$. Thus, we can choose a sequence $(\varepsilon_n)_{n \in \mathbb{N}}$ of positive numbers converging to zero such that $\mathbb{E} \left[\int_0^T \left(\delta_s^{(\varepsilon_n)} \right)^4 ds \right] \leq 2^{-n}$ and therefore

$$\sum_{n=0}^{\infty} p(n) \mathbb{E} \left[\int_0^T \left(\delta_s^{(\varepsilon_n)} \right)^l ds \right] < \infty$$

for all polynomials p and $l \in \{1, 2, 3, 4\}$. In particular $\sum_{n=1}^{\infty} p(n) \int_0^T \delta_s^{(\varepsilon_n)} ds < \infty$ a.s. for all polynomials p .

Set for $n \in \mathbb{N}, (s, y, z) \in [0, T] \times \mathbb{R} \times \mathbb{R}^d$

$$g_n(s, y, z) := \tilde{g}_{\varepsilon_n}(s, y + \sum_{k=0}^{\infty} \int_0^s (k+1) \delta_r^{(\varepsilon_{n+k})} dr, z),$$

and accordingly

$$f_n(s, y, z) := \tilde{f}_{\varepsilon_n}(s, y + \sum_{k=0}^{\infty} \int_0^s (k+1) \delta_r^{(\varepsilon_{n+k})} dr, z).$$

Defining $\alpha_s^{(n)} := \sum_{k=0}^{\infty} \delta_s^{(\varepsilon_{n+k})}$ and $\beta_s^{(n)} := \sum_{k=0}^{\infty} (k+1) \delta_s^{(\varepsilon_{n+k})} = \sum_{l=n}^{\infty} \alpha_s^{(l)}$ we have

$$\begin{aligned} f_n(s, y, z) &= \tilde{f}_{\varepsilon_n}(s, y + \int_0^s \beta_r^{(n)} dr, z) \leq f(s, y + \int_0^s \beta_r^{(n)} dr, z) + \delta_s^{(\varepsilon_n)} \leq \\ &\leq \tilde{f}_{\varepsilon_{n+1}}(s, y + \int_0^s \beta_r^{(n)} dr, z) + \delta_s^{(\varepsilon_n)} + \delta_s^{(\varepsilon_{n+1})} \leq \\ &\leq f_{n+1}(s, y + \int_0^s \beta_r^{(n)} dr - \int_0^s \beta_r^{(n+1)} dr, z) + \sum_{k=0}^{\infty} \delta_s^{(\varepsilon_{n+k})} = \\ &= f_{n+1}(s, y + \int_0^s \alpha_r^{(n)} dr, z) + \alpha_s^{(n)}. \end{aligned}$$

This means

$$f_n(s, y, z) \leq f_{n+1}(s, y + \int_0^s \alpha_r^{(n)} dr, z) + \alpha_s^{(n)},$$

a form of monotonicity we will use later. We have also shown

$$f_n(s, y, z) \leq f(s, y + \int_0^s \beta_r^{(n)} dr, z) + \beta_s^{(n)}, \quad s \in [0, T], y \in \mathbb{R}, z \in \mathbb{R}^d.$$

Note in addition that $\mathbb{E} \left[\left(\int_0^T \beta_s^{(n)} ds \right)^4 \right] < \infty$ for all n since by Hölder's inequality

$$\left(\int_0^T \beta_s^{(0)} ds \right)^4 \leq T^3 \int_0^T \left(\beta_s^{(0)} \right)^4 ds,$$

and again by Hölder's inequality

$$\left(\sum_{k=0}^{\infty} (k+1) \delta_s^{(\varepsilon_k)} \right)^4 \leq \left(\sum_{k=0}^{\infty} \left(\frac{1}{(k+1)^{3/2}} \right)^{4/3} \right)^3 \left(\sum_{k=0}^{\infty} \left((k+1)^{\frac{3}{2}} (k+1) \delta_s^{(\varepsilon_k)} \right)^4 \right)$$

$$\text{and } \mathbb{E} \left[\int_0^T \sum_{n=0}^{\infty} (n+1)^{10} \left(\delta_s^{(\varepsilon_n)} \right)^4 ds \right] < \infty.$$

Since $\sum_{n=1}^{\infty} \int_0^T n \delta_s^{(\varepsilon_n)} ds < \infty$ a.s. we have $\lim_{n \rightarrow \infty} \int_0^s \beta_r^{(n)} dr = 0$ for a.a. (ω, s) .

Furthermore, since $g(\omega, s, \cdot, \cdot)$ is uniformly continuous on compact sets, which are disjoint from $\{(y, z) | y \in \mathbb{R}, z = 0 \in \mathbb{R}^d\}$ and $\tilde{g}_\varepsilon(\omega, s, \cdot, \cdot)$ converges for $\varepsilon \rightarrow 0$ uniformly to $g(\omega, s, \cdot, \cdot)$ on such compacts, $g_n(\omega, s, \cdot, \cdot)$ converges uniformly to g on such compacts as well (for a.a. (ω, s)) as $n \rightarrow \infty$.

In addition, for $n \in \mathbb{N}$, f_n is Lipschitz continuous in (y, z) according to the definition of \tilde{g}_ε and \tilde{f}_ε . In fact, for $s \in [0, T], y \in \mathbb{R}, z \in \mathbb{R}^d$

$$\begin{aligned} \tilde{f}_\varepsilon(s, y, z) &= \\ &= \int_{\mathbb{R} \times \mathbb{R}^d} (z - \hat{z}) g(s, y - \hat{y}, z - \hat{z}) \rho_\varepsilon(\hat{y}, \hat{z}) d(\hat{y}, \hat{z}) + \int_{\mathbb{R} \times \mathbb{R}^d} \hat{z} g(s, y - \hat{y}, z - \hat{z}) \rho_\varepsilon(\hat{y}, \hat{z}) d(\hat{y}, \hat{z}) = \\ &= \int_{\mathbb{R} \times \mathbb{R}^d} f(s, \hat{y}, \hat{z}) \rho_\varepsilon(y - \hat{y}, z - \hat{z}) d(\hat{y}, \hat{z}) + \int_{\mathbb{R} \times \mathbb{R}^d} g(s, \hat{y}, \hat{z}) (z - \hat{z}) \rho_\varepsilon(y - \hat{y}, z - \hat{z}) d(\hat{y}, \hat{z}) = \\ &= f * \rho_\varepsilon(s, y, z) + (g * (z \rho_\varepsilon))(s, y, z), \end{aligned}$$

which means that \tilde{f}_ε is differentiable with respect to (y, z) with uniformly bounded derivatives, since f, g and the derivatives of ρ_ε and $z\rho_\varepsilon$ are all uniformly bounded. Furthermore \tilde{f}_ε and therefore f_n are uniformly bounded.

Similarly g_n is Lipschitz continuous and uniformly bounded for $n \in \mathbb{N}$, because the $\tilde{g}_\varepsilon, \varepsilon > 0$, possess this property.

STEP3 We now apply Theorem 2.2 to show the existence of some a.-measure solution \mathbb{Q} of the BSDE given by g and ξ . Since for $n \in \mathbb{N}$ the approximations f_n, g_n are Lipschitz continuous there exists a measure solution \mathbb{Q}_n of the BSDE given by g_n and $\xi - \int_0^T \beta_s^{(n)} ds =: \xi_n$. This is guaranteed by a slight extension (including y as a variable in the generator) of the relationship between classical and measure solution explained in [3] in the case of Lipschitz continuous generator. We check the validity of the hypotheses of Theorem 2.2.

Condition *i*):

For $n \in \mathbb{N}$ define

$$R_n := \exp \left(\int_0^T g_n(s, Y_s^n, Z_s^n) dW_s - \frac{1}{2} \int_0^T |g_n(s, Y_s^n, Z_s^n)|^2 ds \right).$$

We have to show

$$\sup_n \mathbb{E}[R_n^p] + \sup_n \mathbb{E}[R_n^{1-p}] < \infty.$$

But this holds for all $p > 1$ as a consequence of the uniform boundedness of g_n .

Condition *ii*) holds for $q = 2$ by dominated convergence.

Condition *iii*):

It is sufficient to show monotonicity of $(Y^n)_{n \in \mathbb{N}}$ and boundedness of $(\|Y^n\|_{\mathcal{H}^2(\mathbb{R}, \mathbb{P})})_{n \in \mathbb{N}}$. The latter follows from the boundedness of $(\|\xi_n\|_{L^2(\mathbb{R}, \mathbb{P})})_{n \in \mathbb{N}}$. We will now show monotonicity using the comparison theorem:

For $n \in \mathbb{N}$ define $X^n := Y^n + \int_0^\cdot \alpha_r^{(n)} dr$. Since

$$Y^n = \xi_n + \int^\cdot f_n(r, Y_r^n, Z_r^n) dr - \int^\cdot Z_r^n dW_r,$$

we also have

$$X^n = \xi_n + \int_0^T \alpha_r^{(n)} dr + \int^\cdot \left(f_n(r, Y_r^n, Z_r^n) - \alpha_r^{(n)} \right) dr - \int^\cdot Z_r^n dW_r.$$

Note $\xi_n + \int_0^T \alpha_r^{(n)} dr = \xi_{n+1}$ and for $r \in [0, T]$

$$f_n(r, Y_r^n, Z_r^n) - \alpha_r^{(n)} \leq f_{n+1}(r, Y_r^n + \int_0^r \alpha_v^{(n)} dv, Z_r^n) = f_{n+1}(r, X_r^n, Z_r^n)$$

according to arguments in STEP2. If we now consider the two standard Lipschitz BSDE given by the generators defined by $\varphi(r, y, z) := f_n(r, Y_r^n, Z_r^n) - \alpha_r^{(n)}$ and $\psi(r, y, z) = f_{n+1}(r, y, z)$, $r \in [0, T], y \in \mathbb{R}, z \in \mathbb{R}^d$, and by the identical terminal condition ξ_{n+1} , we see that the first one is solved (in the classical sense) by (X^n, Z^n) and the second one by (Y^{n+1}, Z^{n+1}) , and at the same time $\varphi(r, X_r^n, Z_r^n) \leq \psi(r, X_r^n, Z_r^n)$, $r \in [0, T]$. The comparison theorem implies $X^n \leq Y^{n+1}$ a.e., and therefore $Y^n \leq Y^{n+1}$ a.e.

Condition *iv*): Its validity has been discussed in STEP2.

Thus Theorem 2.2 is applicable, and there exists an a.-measure solution of the BSDE given by ξ and g . But since g is bounded, there must exist a measure solution \mathbb{Q} with the same Y and Z , according to Remark 1.7. \square

Corollary 3.2. *The measure solution $\tilde{\mathbb{Q}}$ constructed above is minimal in the following sense: for all classical solutions (\tilde{Y}, \tilde{Z}) of the BSDE corresponding to $(\tilde{f}, \tilde{\xi})$ where \tilde{f} is any bounded generator such that $f \leq \tilde{f}$ and $\xi \leq \tilde{\xi} \in L^2(\mathbb{P})$ we have $Y \leq \tilde{Y}$ a.e. with $Y := \mathbb{E}_{\tilde{\mathbb{Q}}}[\xi | \mathcal{F}] = \lim_{n \rightarrow \infty} Y^n$ from the above construction.*

Proof. For $n \in \mathbb{N}$ define $W^n := \tilde{Y} - \int_0^\cdot \beta_r^{(n)} dr$ and conclude that (W^n, \tilde{Z}) solves (in the classical sense) the BSDE given by the generator $\varphi(r, y, z) := \tilde{f}(r, \tilde{Y}_r, \tilde{Z}_r) + \beta_r^{(n)}$, $r \in [0, T]$, $y \in \mathbb{R}$, $z \in \mathbb{R}^d$, and $\tilde{\xi} - \int_0^T \beta_r^{(n)} dr =: \tilde{\xi}_n$. We know for $s \in [0, T]$, $y \in \mathbb{R}$, $z \in \mathbb{R}^d$

$$f_n(s, y, z) \leq f(s, y + \int_0^s \beta_r^{(n)} dr, z) + \beta_s^{(n)}$$

and therefore for $r \in [0, T]$ $f_n(r, W_r^n, \tilde{Z}_r) \leq f(r, \tilde{Y}_r, \tilde{Z}_r) + \beta_r^{(n)} \leq \varphi(r, W_r^n, \tilde{Z}_r)$. Also note $\xi_n \leq \tilde{\xi}_n$. By the comparison theorem this implies $Y^n \leq W^n$ a.e. This in turn entails the a.e. relation

$$Y = \lim_{n \rightarrow \infty} Y^n \leq \lim_{n \rightarrow \infty} W^n = \tilde{Y}.$$

□

As a consequence of this, minimal solutions are unique.

Corollary 3.3. *Minimal measure solutions according to Corollary 3.2 are unique in the sense that (Y, Z) are uniquely determined.*

Furthermore the following comparison property holds. For bounded $\xi \leq \hat{\xi}$ and for generators $f(\cdot, y, z) = z \cdot g(\cdot, y, z)$ and $\hat{f}(\cdot, y, z) = z \cdot \hat{g}(\cdot, y, z)$, $y \in \mathbb{R}$, $z \in \mathbb{R}^d$, such that the pairs (g, f) and (\hat{g}, \hat{f}) both satisfy conditions i)-iii) of Theorem 3.1 and such that $f \leq \hat{f}$ pointwise, the corresponding minimal measure solutions satisfy $Y \leq \hat{Y}$ a.e.

In the following lemma, we obtain a stronger result than in Lemma 3.1. In fact, we are able to drop the uniform continuity condition *iii)* of Lemma 3.1.

Lemma 3.4. *Let $\xi \in L^\infty(\mathcal{F}_T)$ be bounded by some constant K . Let g be proper, let g and $f(\cdot, y, z) = z \cdot g(\cdot, y, z)$, $y \in \mathbb{R}$, $z \in \mathbb{R}^d$, be uniformly bounded and let $g(\omega, s, \cdot, \cdot)$ be continuous at all points (y, z) such that $z \neq 0$ for a.a. (ω, s) .*

Then there exists a measure solution of the BSDE given by g and ξ .

Proof. For $s \in [0, T]$, $y \in \mathbb{R}$, $z \in \mathbb{R}^d$ define $\tilde{f}(s, y, z) := f(s, (-K) \vee y \wedge K, z)$ and $\tilde{g}(s, y, z) := g(s, (-K) \vee y \wedge K, z)$. \tilde{g} is proper and $g(\omega, s, \cdot, \cdot)$ is continuous at all points (y, z) such that $z \neq 0$ for a.a. (ω, s) . A measure solution of the BSDE given by \tilde{g} and ξ will be a measure solution of the BSDE given by g and ξ as well, since \tilde{Y} is bounded by K . Hence w.l.o.g we can assume $f = \tilde{f}$ and $g = \tilde{g}$.

Approximate f , which is obviously continuous, from below by f_n , $n \in \mathbb{N}$, which is uniformly bounded and uniformly continuous in (y, z) and such that $f_n(\cdot, y, z) = f(\cdot, y, z)$ for $|y| \leq K$, $|z| \leq 1$, and such that $(f_n)_{n \in \mathbb{N}}$ is pointwise increasing and converges to f uniformly on compact sets S for a.a. (ω, s) . One possible definition for $(f_n)_{n \in \mathbb{N}}$ is given by

$$f_n(\cdot, y, z) := \inf_{\substack{\hat{z} \in \mathbb{R}^d \\ \hat{y} \in [-K, K]}} \left\{ f(\cdot, \hat{y}, \hat{z}) + \frac{n}{0 \vee (|z| - n) \wedge 1} \left| \begin{pmatrix} y \\ z \end{pmatrix} - \begin{pmatrix} \hat{y} \\ \hat{z} \end{pmatrix} \right| \right\}, \quad z \in \mathbb{R}^d, y \in \mathbb{R}, n \in \mathbb{N}, \quad (13)$$

where we use the convention $\frac{n}{0} \cdot 0 := 0$ and $\frac{n}{0} \cdot r := \infty$ for $r > 0$. See Lemma A.7 for details.

Now define $g_n(\cdot, z) := \frac{z}{|z|^2} \mathbf{1}_{\{z \neq 0\}} f_n(\cdot, z)$, $z \in \mathbb{R}^d$, $n \in \mathbb{N}$. We have $g_n(\cdot, 0) = 0$.

Note that $(g_n)_{n \in \mathbb{N}}$ is uniformly bounded. In fact, for $|z| \leq 1$, $|y| \leq K$ we have: $|g_n(\cdot, y, z)| = \frac{1}{|z|} |f_n(\cdot, y, z)| = \frac{1}{|z|} |f(\cdot, y, z)| = \frac{1}{|z|} |z \cdot g(\cdot, y, z)| \leq |g(\cdot, y, z)|$ which is bounded. Furthermore $g_n(\omega, s, \cdot, \cdot)$ converges to $\hat{g}(\omega, s, \cdot, \cdot) := \frac{z}{|z|^2} \mathbf{1}_{\{z \neq 0\}} f(\omega, s, \cdot, \cdot)$ uniformly on compacts not containing points with vanishing z -part for a.e. (ω, s) , because of the convergence of f_n to f .

Considering the BSDEs given by g_n and ξ there exist, according to Lemma 3.1 corresponding (minimal) measure solutions \mathbb{Q}_n . According to Corollary 3.3 for the corresponding Y^n we have the inequality $Y^n \leq Y^{n+1}$ a.e.. Furthermore $(Y^n)_{n \in \mathbb{N}}$ is uniformly bounded by K . Hence condition *iii*) of Theorem 2.1 is satisfied. The remaining three are easy to check. Theorem 2.1 is therefore applicable, and there exists an a.-measure solution of the BSDE given by ξ and \hat{g} . However, since \hat{g} is bounded and for $z \in \mathbb{R}^d$ we have $z\hat{g}(\cdot, z) = zg(\cdot, z)$, there must exist a measure solution of the BSDE given by ξ and g as well, according to Remark 1.7. \square

Corollary 3.5. *The solution (\mathbb{Q}, Y) constructed in Lemma 3.4 is minimal in the following sense. For bounded $\check{\xi} \geq \xi$ and $\check{f}(\cdot, z) = z \cdot \check{g}(\cdot, z)$, $z \in \mathbb{R}^d$, such that the pair (\check{g}, \check{f}) satisfies the conditions of Lemma 3.4 and such that $f \leq \check{f}$ pointwise, we have for a measure solution $\check{\mathbb{Q}}: Y \leq \check{Y}$ a.e., where \check{Y} corresponds to $\check{\mathbb{Q}}$ and $\check{\xi}$ in the sense of section 1.*

Proof. This is easily shown by means of the approximating generators f_n from the proof of Lemma 3.4 satisfying $f_n \leq \check{f}$, $n \in \mathbb{N}$. This implies $Y^n \leq \check{Y}$ by Corollary 3.3. Therefore $Y = \lim_{n \rightarrow \infty} Y^n \leq \check{Y}$. \square

In the following main existence theorem of this paper the statement of the preceding lemma is extended to generating functions g that are not uniformly bounded. We are able to treat cases in which the upper bound on $|g(s, \cdot, z)|$ is at most proportional to $|z|$ and provided by a progressive process ϕ such that its stochastic integral with respect to W generates a BMO martingale. More precisely, we have

Theorem 3.1. *Let $\xi \in L^\infty(\mathcal{F}_T)$. Let g be proper, assume that $g(\omega, s, \cdot, \cdot)$ is continuous at all points (y, z) such that $z \neq 0$ for a.a. (ω, s) , and $|g(s, \cdot, z)| \leq C(|z| + \phi_s)$, $s \in [0, T]$, $z \in \mathbb{R}^d$, with some progressive $\phi \in BMO(\mathbb{P})$ (see Appendix A) and a constant $C > 0$.*

Then there exists a measure solution of the BSDE given by g and ξ .

Proof. Note that $f(\omega, s, y, z) := z \cdot g(\omega, s, y, z)$ is continuous in $(y, z) \in \mathbb{R} \times \mathbb{R}^d$ for a.a. $(\omega, s) \in \Omega \times [0, T]$, where the continuity at points $(y, 0)$ comes from $|f(s, y, z)| \leq C|z|(|z| + \phi_s)$.

For $z \in \mathbb{R}^d$ define $\tilde{g}(\cdot, z) := \frac{z}{|z|^2} \mathbf{1}_{\{z \neq 0\}} f(\cdot, z)$ (where $\frac{z}{|z|^2} \mathbf{1}_{\{z \neq 0\}}$ is defined to be 0 at $z = 0$). Note that \tilde{g} also satisfies $|\tilde{g}(s, \cdot, z)| \leq C(|z| + \phi_s)$, $s \in [0, T]$, $z \in \mathbb{R}^d$.

For $n, m \in \mathbb{N}$, $s \in [0, T]$, $y \in \mathbb{R}$, $z \in \mathbb{R}^d$ define

$$f_{nm}(s, y, z) := (-n) \vee \left(|z| \cdot (-n) \vee \left(\frac{1}{|z|} f(s, y, z) \right) \wedge m \right) \wedge m,$$

$$g_{nm}(s, y, z) := \frac{z}{|z|^2} \mathbf{1}_{\{z \neq 0\}} f_{nm}(s, y, z).$$

For all $n, m \in \mathbb{N}$, the functions f_{nm} and g_{nm} are bounded. This follows from

$$|g_{nm}(\cdot, z)| \leq \frac{1}{|z|} |f_{nm}(\cdot, z)| \leq \left| (-n) \vee \left(\frac{1}{|z|} f(\cdot, z) \right) \wedge m \right|.$$

Furthermore

$$f_{nm}(s, \cdot, z) \leq C(|z|^2 + |z|\phi_s), \quad s \in [0, T], z \in \mathbb{R}^d.$$

The double sequence $(f_{nm})_{n,m \in \mathbb{N}}$ is pointwise non-decreasing in m for fixed n , and non-increasing in n for fixed m . According to Lemma 3.4 and the associated corollary there exist minimal measure solutions \mathbb{Q}_{nm} of the BSDEs given by g_{nm} and ξ , $n, m \in \mathbb{N}$. The corresponding double sequence $(Y^{nm})_{n,m \in \mathbb{N}}$ is non-decreasing in m and non-increasing in n according to Corollary 3.5. For $n \in \mathbb{N}$ define $\tilde{Y}^n := \lim_{m \rightarrow \infty} Y^{nm}$. We next apply Theorem 2.2 to show the existence of a.-measure solutions of the BSDE given by $g_n := \lim_{m \rightarrow \infty} g_{nm}$ and ξ . Note that g_n is associated with

$$f_n(\cdot, z) := (-n) \vee \left(|z| \cdot (-n) \vee \left(\frac{1}{|z|} f(\cdot, z) \right) \right),$$

$$g_n(\cdot, z) = \frac{z}{|z|^2} \mathbf{1}_{\{z \neq 0\}} f_n(\cdot, z) \quad z \in \mathbb{R}^d.$$

Let us verify the hypotheses of Theorem 2.2.

Condition *i)*: According to Lemma A.3 applied to the BSDE given by f_{nm} and ξ , the control processes Z^{nm} are in $BMO(\mathbb{P})$ with a uniformly bounded BMO-norm, $n, m \in \mathbb{N}$. Using Lemmas A.1 and A.2 there must exist a $p > 1$ such that *i)* is satisfied.

Condition *ii)* holds trivially.

Condition *iii)* holds by dominated convergence and uniform boundedness of $(Y^{nm})_{n,m \in \mathbb{N}}$.

Condition *iv)* holds according to the construction of $(g_{nm})_{n,m \in \mathbb{N}}$.

Theorem 2.2 provides a.-measure solutions \mathbb{Q}_n of the BSDE given by g_n and ξ and we have the associated solution pair (Y^n, Z^n) , $n \in \mathbb{N}$. We have

$$Y^n := \lim_{m \rightarrow \infty} Y^{nm} = \mathbb{E}_{\mathbb{Q}_n}[\xi | \mathcal{F}]$$

according to Remark 2.5. Furthermore according to Remark 2.6 for any $n \in \mathbb{N}$ Z_n is in $BMO(\mathbb{P})$ with a BMO-norm uniformly bounded in n , since Z_n results from an a.e.-limit of processes with uniformly bounded BMO-norms (see Lemma A.4).

Note that $Y^{nm} \geq Y^{n'm}$ a.e. for all $m \in \mathbb{N}$ and $n < n'$ implies $Y^n \geq Y^{n'}$ a.e.. Thus $(Y^n)_{n \in \mathbb{N}}$ converges to some limit \tilde{Y} , and we can similarly apply Theorem 2.2 to $(\mathbb{Q}_n, g_n, Y^n)_{n \in \mathbb{N}}$ to construct an a.-measure solution of the BSDE given by \tilde{g} and ξ . For its applicability we use Remark 2.4.

This means that there exists an a.-measure solution \mathbb{Q} of the BSDE given by \tilde{g} and ξ . Using Remark 2.6 as well as Lemma A.4, we can assume that the corresponding control process \tilde{Z} is in $BMO(\mathbb{P})$.

Now define $\zeta := g(\cdot, \tilde{Y}, \tilde{Z})$. Then $\zeta \in BMO(\mathbb{P})$ and hence $\mathbb{Q} := \mathcal{E}(\zeta \bullet W)_T \cdot \mathbb{P}$ is a probability measure. Thus it is a measure solution of the BSDE given by g and ξ according to Remark 1.7. \square

A Appendix

We collect some well known facts and extensions about BMO, exponential martingales and normed spaces. The BMO prerequisites are needed for the derivation of our main existence results for measure solutions in the preceding section, and underpin the fact that this class of martingales plays a very important role in concepts of control theory. The first topic we address is concerned with integrability properties of the exponentials of BMO martingales.

Lemma A.1. *For $K > 0$ there exist real constants $r < 0$ and $C > 0$ such that*

$$\mathbb{E}[\mathcal{E}(M)_T^r] \leq C$$

for all BMO-martingales $M = Z \bullet W := \int_0^\cdot Z_s dW_s$ satisfying $\|Z\|_{BMO(\mathbb{P})} \leq K$.

Proof. Indeed, we may write for real r

$$\begin{aligned} & \mathbb{E} \left[\exp \left(rM_T - r \frac{1}{2} \langle M \rangle_T \right) \right] = \mathbb{E} \left[\exp (rM_T - \langle rM \rangle_T) \exp \left(\left(r^2 - \frac{r}{2} \right) \langle M \rangle_T \right) \right] \leq \\ & \leq \left(\mathbb{E} \left[\exp \left(2rM_T - \frac{1}{2} \langle 2rM \rangle_T \right) \right] \right)^{\frac{1}{2}} \left(\mathbb{E} [\exp (r(2r-1) \langle M \rangle_T)] \right)^{\frac{1}{2}} = \left(\mathbb{E} [\exp (\hat{r} \langle M \rangle_T)] \right)^{\frac{1}{2}} \end{aligned}$$

with $\hat{r} := r(2r-1)$. Now define $r := \frac{1}{4} - \sqrt{\frac{1}{16} + \frac{1}{4K^2}} < 0$ and $C := \sqrt{2}$. Then $\hat{r} = \frac{1}{2K^2}$. Setting $\tilde{Z} := \sqrt{\hat{r}}Z$, we have $\|\tilde{Z}\|_{BMO(\mathbb{P})}^2 \leq \frac{1}{2}$ if $\|Z\|_{BMO(\mathbb{P})} \leq K$.

Then according to Theorem 2.2. of [17]

$$\mathbb{E} \left[\exp \left(\hat{r} \int_0^T |Z_t|^2 dt \right) \right] = \mathbb{E} \left[\exp \left(\int_0^T |\tilde{Z}_t|^2 dt \right) \right] \leq \frac{1}{1 - \|\tilde{Z}\|_{BMO(\mathbb{P})}^2} \leq 2 = C^2.$$

□

Lemma A.2. For $K > 0$ there exist real $p > 1$ and $C > 0$ such that

$$\mathbb{E}[\mathcal{E}(M)_T^p] \leq C$$

for all BMO-martingales $M = Z \bullet W$ satisfying $\|Z\|_{BMO(\mathbb{P})} \leq K$.

Proof. According to the proof of Theorem 3.1. of [17] the inequality $\|Z\|_{BMO(\mathbb{P})} < \Phi(p)$ would imply

$$\mathbb{E}[\mathcal{E}(M)_T^p] \leq \frac{2}{1 - 2(p-1)(2p-1)^{-1} \exp(p^2 \|Z\|_{BMO(\mathbb{P})} (2 + \|Z\|_{BMO(\mathbb{P})}))} < \infty$$

with

$$\Phi(p) := \left(1 + \frac{1}{p^2} \ln \frac{2p-1}{2(p-1)} \right)^{\frac{1}{2}} - 1$$

for $p > 1$.

Note that $\|Z\|_{BMO(\mathbb{P})} < \Phi(p)$ also implies

$$\|Z\|_{BMO(\mathbb{P})} (2 + \|Z\|_{BMO(\mathbb{P})}) = (\|Z\|_{BMO(\mathbb{P})} + 1)^2 - 1 < \frac{1}{p^2} \ln \frac{2p-1}{2(p-1)}$$

Since $\lim_{p \rightarrow 1} \Phi(p) = \infty$ we can choose $p > 1$ such that $K < \Phi(p)$. This proves the assertion. □

The following result extends Proposition 7.3 in [9]. It provides conditions on the increase rate of the drift term of a stochastic equation which give bounds on the BMO norm of its stochastic integral part.

Lemma A.3. Let Y, Z, X, ψ, φ be some progressive processes such that Y is bounded and

$$Y_t = Y_T + \int_t^T X_s ds - \int_t^T Z_s dW_s \quad \text{a.s. } \forall t \in [0, T].$$

Let $X \leq \psi^2 + |Z|\varphi + C|Z|^2$ with some $C > 0$ and $\varphi, \psi \in BMO(\mathbb{P})$.

Then there exists a constant K which only depends on $\|\varphi\|_{BMO(\mathbb{P})} \vee \|\psi\|_{BMO(\mathbb{P})} \vee C \vee \|Y\|_\infty$ such that $\|Z\|_{BMO(\mathbb{P})} \leq K$.

Proof. By hypothesis

$$X \leq \psi^2 + |Z|\varphi + C|Z|^2 \leq (\psi^2 + \frac{1}{2}\varphi^2) + (C + \frac{1}{2})|Z|^2.$$

Define $\tilde{\psi} := \sqrt{\psi^2 + \frac{1}{2}\varphi^2} \in BMO(\mathbb{P})$ and $\tilde{C} := C + \frac{1}{2}$.

For $0 \leq t \leq T$ we can write

$$Y_t = Y_0 - \int_0^t X_s ds + \int_0^t Z_s dW_s.$$

Let $\beta \in \mathbb{R}$. Using Itô's formula we have

$$\exp(\beta Y_t) = \exp(\beta Y_0) - \int_0^t \beta \exp(\beta Y_s) X_s ds + \int_0^t \beta \exp(\beta Y_s) Z_s dW_s + \frac{\beta^2}{2} \int_0^t \exp(\beta Y_s) |Z_s|^2 ds$$

or

$$\exp(\beta Y_t) = \exp(\beta Y_T) + \int_t^T \beta \exp(\beta Y_s) X_s ds - \int_t^T \beta \exp(\beta Y_s) Z_s dW_s - \frac{\beta^2}{2} \int_t^T \exp(\beta Y_s) |Z_s|^2 ds.$$

We obtain

$$\beta \int_t^T \exp(\beta Y_s) \left(\frac{\beta}{2} |Z_s|^2 - X_s \right) ds = \exp(\beta Y_T) - \exp(\beta Y_t) - \int_t^T \beta \exp(\beta Y_s) Z_s dW_s,$$

and thus by hypothesis

$$\begin{aligned} & \beta \int_t^T \exp(\beta Y_s) \left(\frac{\beta}{2} |Z_s|^2 + \tilde{\psi}_s^2 - X_s \right) ds = \\ & = \exp(\beta Y_T) - \exp(\beta Y_t) + \beta \int_t^T \exp(\beta Y_s) \tilde{\psi}_s^2 ds - \int_t^T \beta \exp(\beta Y_s) Z_s dW_s. \end{aligned}$$

Setting $\beta := 2\tilde{C} + 2 = 2C + 3$ we have

$$|Z|^2 \leq \frac{\beta}{2} |Z|^2 + \tilde{\psi}^2 - X.$$

Applying conditional expectations we get for $0 \leq t \leq T$

$$\begin{aligned} & \mathbb{E} \left[\beta \int_t^T \exp(\beta Y_s) |Z_s|^2 ds \middle| \mathcal{F}_t \right] \leq \\ & \leq \mathbb{E} \left[\exp(\beta Y_T) - \exp(\beta Y_t) + \beta \int_t^T \exp(\beta Y_s) (\psi^2 + \frac{1}{2}\varphi^2) ds \middle| \mathcal{F}_t \right]. \end{aligned}$$

Since $\exp(\beta Y)$ is bounded from below and from above and since $\psi, \varphi \in BMO(\mathbb{P})$ this shows $\|Z\|_{BMO(\mathbb{P})} \leq K < \infty$, with some K which can be already determined by only knowing an upper bound for β , $\|Y\|_\infty$, $\|\psi\|_{BMO(\mathbb{P})}$ and $\|\varphi\|_{BMO(\mathbb{P})}$ and a lower bound for β (which is 3). \square

The following is a Fatou type property of BMO norms.

Lemma A.4. *Let (Z^n) be a sequence of progressive processes converging to some progressive Z in measure (w.r.t. $\mathbb{P} \otimes \lambda_{[0,T]}$). Then $\|Z\|_{BMO(\mathbb{P})} \leq \liminf_{n \rightarrow \infty} \|Z^n\|_{BMO(\mathbb{P})}$.*

Proof. Assume the contrary. Then there must exist a subsequence (Z^{n_k}) s.t. $\|Z\|_{BMO(\mathbb{P})} > \liminf_{k \rightarrow \infty} \|Z^{n_k}\|_{BMO(\mathbb{P})}$ and $Z^{n_k} \rightarrow Z$ a.e. for $k \rightarrow \infty$. However by Fatou's inequality we have for $0 \leq t \leq T$

$$\mathbb{E} \left[\int_t^T |Z_s|^2 ds \middle| \mathcal{F}_t \right] \leq \liminf_{k \rightarrow \infty} \mathbb{E} \left[\int_t^T |Z_s^{n_k}|^2 ds \middle| \mathcal{F}_t \right] \leq \liminf_{k \rightarrow \infty} \|Z^{n_k}\|_{BMO(\mathbb{P})}$$

almost surely. This implies $\|Z\|_{BMO(\mathbb{P})} \leq \liminf_{k \rightarrow \infty} \|Z^{n_k}\|_{BMO(\mathbb{P})}$, yielding a contradiction. \square

Next is the well-known representation property of exponential martingales on a Brownian basis.

Lemma A.5. *Let $\mathbb{Q} \sim \mathbb{P}$ be a probability measure. Define $R_T := \frac{d\mathbb{Q}}{d\mathbb{P}}$ as the Radon-Nikodym derivative. Then the martingale $R := \mathbb{E}[R_T | \mathcal{F}]$ can be written as*

$$R = \exp \left(\int_0^\cdot \zeta_s dW_s - \frac{1}{2} \int_0^\cdot |\zeta_s|^2 ds \right)$$

with some progressively measurable process ζ such that $\int_0^T |\zeta_s|^2 ds < \infty$ a.s.

Proof. This is a consequence of Proposition 1.6 of Chapter VIII in [19] and the martingale representation theorem. \square

We next recall a well known dual characterization of Hölder norms.

Lemma A.6. *Let \mathbb{Q} be a probability measure on (Ω, \mathcal{F}) . Let Y be non-negative and \mathcal{F} -measurable. Let $p, q > 1$ such that $\frac{1}{p} + \frac{1}{q} = 1$. Denote \mathcal{X} the set of all bounded \mathcal{F} -measurable $X > 0$. Then*

$$\mathbb{E}_{\mathbb{Q}}[Y^p]^{\frac{1}{p}} = \sup_{X \in \mathcal{X}} \frac{\mathbb{E}_{\mathbb{Q}}[Y \cdot X]}{\mathbb{E}_{\mathbb{Q}}[X^q]^{\frac{1}{q}}}.$$

Proof. First use Hölder's inequality to get

$$\frac{\mathbb{E}_{\mathbb{Q}}[Y \cdot X]}{\mathbb{E}_{\mathbb{Q}}[X^q]^{\frac{1}{q}}} \leq \frac{(\mathbb{E}_{\mathbb{Q}}[Y^p])^{\frac{1}{p}} (\mathbb{E}_{\mathbb{Q}}[X^q])^{\frac{1}{q}}}{\mathbb{E}_{\mathbb{Q}}[X^q]^{\frac{1}{q}}}.$$

This implies

$$\sup_{X \in \mathcal{X}} \frac{\mathbb{E}_{\mathbb{Q}}[Y \cdot X]}{\mathbb{E}_{\mathbb{Q}}[X^q]^{\frac{1}{q}}} \leq \mathbb{E}_{\mathbb{Q}}[Y^p]^{\frac{1}{p}}.$$

Secondly, defining for $n, m \in \mathbb{N}$ the bounded and positive $X_{nm} := (\frac{1}{m} + Y \wedge n)^{p-1}$, and assuming $0 < \mathbb{E}_{\mathbb{Q}}[Y] < \infty$ for a moment, we may write

$$\begin{aligned} \sup_{X \in \mathcal{X}} \frac{\mathbb{E}_{\mathbb{Q}}[Y \cdot X]}{(\mathbb{E}_{\mathbb{Q}}[X^q])^{\frac{1}{q}}} &\geq \sup_{n, m} \frac{\mathbb{E}_{\mathbb{Q}}[Y \cdot X_{nm}]}{(\mathbb{E}_{\mathbb{Q}}[X_{nm}^q])^{\frac{1}{q}}} \geq \lim_{n \rightarrow \infty} \lim_{m \rightarrow \infty} \frac{\mathbb{E}_{\mathbb{Q}}[(Y \wedge n) \cdot X_{nm}]}{(\mathbb{E}_{\mathbb{Q}}[X_{nm}^q])^{\frac{1}{q}}} = \\ &= \lim_{n \rightarrow \infty} \frac{\mathbb{E}_{\mathbb{Q}}[(Y \wedge n) \cdot (Y \wedge n)^{p-1}]}{(\mathbb{E}_{\mathbb{Q}}[(Y \wedge n)^{(p-1)q})^{\frac{1}{q}}} = \lim_{n \rightarrow \infty} (\mathbb{E}_{\mathbb{Q}}[(Y \wedge n)^p])^{\frac{1}{p}} = (\mathbb{E}_{\mathbb{Q}}[Y^p])^{\frac{1}{p}}. \end{aligned}$$

Here we use $\mathbb{E}_{\mathbb{Q}}[(Y \wedge n)^p] > 0$ for n large enough.

Now if $\mathbb{E}_{\mathbb{Q}}[Y] = 0$ the claim is trivial, since this implies $Y = 0$ \mathbb{Q} -a.s.

If $\mathbb{E}_{\mathbb{Q}}[Y] = \infty$ the claim becomes trivial as well, since then $\mathbb{E}_{\mathbb{Q}}[Y^p] = \infty$ and we can set $X = 1$. \square

We finally show that the regularization of a continuous function f by (13) indeed yields a sequence of uniformly continuous functions converging monotonously to f . Denote by \bar{A} the closure of a set A in a topological space.

Lemma A.7. *Let $R, M > 0$, and let $f : [-R, R] \times \mathbb{R}^m \rightarrow \mathbb{R}$ be bounded by M and continuous. Define $f_n : [-R, R] \times \mathbb{R}^m \rightarrow \mathbb{R}$ by*

$$f_n(y, z) = \inf_{\hat{z} \in \mathbb{R}^m, \hat{y} \in [-R, R]} \left\{ f(\hat{y}, \hat{z}) + \frac{n}{0 \vee (|z| - n) \wedge 1} \left| \begin{pmatrix} y \\ z \end{pmatrix} - \begin{pmatrix} \hat{y} \\ \hat{z} \end{pmatrix} \right| \right\}, \quad z \in \mathbb{R}^d, y \in \mathbb{R}, n \in \mathbb{N},$$

with the conventions of (13). Then we have

- (i) f_n is bounded by M for any $n \in \mathbb{N}$,
- (ii) $f_n = f$ on $[-R, R] \times \overline{B_n(0)}$,
- (iii) f_n is uniformly continuous for any $n \in \mathbb{N}$,
- (iv) $f_n \leq f_{n+1} \leq f$ for any $n \in \mathbb{N}$.

Proof. (i): This follows from the inequality

$$-M \leq \inf_{\hat{z} \in \mathbb{R}^m, \hat{y} \in \overline{B_R(0)}} \left\{ -M + \frac{n}{0 \vee (|z| - n) \wedge 1} \left| \begin{pmatrix} y \\ z \end{pmatrix} - \begin{pmatrix} \hat{y} \\ \hat{z} \end{pmatrix} \right| \right\} \leq f_n(y, z) \leq f(y, z) \leq M,$$

valid for $y \in \mathbb{R}, z \in \mathbb{R}^m$.

(ii): Note that for $|z| \leq n$ we have $\frac{n}{0 \vee (|z| - n) \wedge 1} = \infty$, and therefore for $|z| \leq n, y \in \overline{B_R(0)}$

$$f_n(y, z) = \inf_{\hat{z} \in \mathbb{R}^m, \hat{y} \in \overline{B_R(0)}} \left\{ f(\hat{y}, \hat{z}) + \frac{n}{0 \vee (|z| - n) \wedge 1} \left| \begin{pmatrix} y \\ z \end{pmatrix} - \begin{pmatrix} \hat{y} \\ \hat{z} \end{pmatrix} \right| \right\} = f(y, z).$$

(iv): For $z \in \mathbb{R}^m, n \in \mathbb{N}$ we note $|z| - n \geq |z| - (n + 1)$, and hence

$$\frac{n}{0 \vee (|z| - n) \wedge 1} \leq \frac{n + 1}{0 \vee (|z| - (n + 1)) \wedge 1} \leq \infty.$$

This implies $f_n \leq f_{n+1} \leq f$.

(iii): For $n \in \mathbb{N}, t \geq 0$ denote $\phi_n(t) = \frac{n}{0 \vee (t - n) \wedge 1}$. Then

$$\phi_n(t) = \begin{cases} \infty, & t \leq n, \\ \frac{n}{t - n}, & n < t \leq n + 1, \\ n, & t > n + 1, \end{cases}$$

and hence for any $\epsilon > 0$ ϕ_n is bounded and Lipschitz continuous on $[n + \epsilon, \infty)$. Hence for any $\epsilon > 0$ and $\hat{z} \in \mathbb{R}^m, \hat{y} \in \overline{B_R(0)}$ the mapping

$$A_{\hat{z}, \hat{y}} : \overline{B_R(0)} \times (\mathbb{R}^m \setminus B_{n+\epsilon}(0)) \ni (y, z) \mapsto \phi_n(|z|) \left| \begin{pmatrix} y \\ z \end{pmatrix} - \begin{pmatrix} \hat{y} \\ \hat{z} \end{pmatrix} \right|$$

is Lipschitz continuous with Lipschitz constant L_ϵ independent of $\hat{y} \in \overline{B_R(0)}, \hat{z} \in \mathbb{R}^m$. To abbreviate, let $M_\epsilon = \overline{B_R(0)} \times (\mathbb{R}^m \setminus B_{n+\epsilon}(0))$. Then we can write for $(y, z), (y', z') \in M_\epsilon, n \in \mathbb{N}$

$$f(\hat{y}, \hat{z}) + \phi_n(|z|) \left| \begin{pmatrix} y \\ z \end{pmatrix} - \begin{pmatrix} \hat{y} \\ \hat{z} \end{pmatrix} \right| \leq f(\hat{y}, \hat{z}) + \phi_n(|z'|) \left| \begin{pmatrix} y' \\ z' \end{pmatrix} - \begin{pmatrix} \hat{y} \\ \hat{z} \end{pmatrix} \right| + L_\epsilon \left| \begin{pmatrix} y \\ z \end{pmatrix} - \begin{pmatrix} y' \\ z' \end{pmatrix} \right|,$$

from which we deduce by eventually switching the roles of (y, z) and (y', z')

$$\begin{aligned} f_n(y, z) &\leq f_n(y', z') + L_\epsilon \left| \begin{pmatrix} y \\ z \end{pmatrix} - \begin{pmatrix} y' \\ z' \end{pmatrix} \right|, \\ f_n(y', z') &\leq f_n(y, z) + L_\epsilon \left| \begin{pmatrix} y \\ z \end{pmatrix} - \begin{pmatrix} y' \\ z' \end{pmatrix} \right|, \end{aligned}$$

and therefore

$$|f_n(y, z) - f_n(y', z')| \leq L_\epsilon \left| \begin{pmatrix} y \\ z \end{pmatrix} - \begin{pmatrix} y' \\ z' \end{pmatrix} \right|.$$

As a conclusion we obtain that for $\epsilon > 0$ f_n is Lipschitz continuous on M_ϵ , and therefore uniformly continuous. As $(\overline{B_R(0)} \times \mathbb{R}^m) \setminus M_\epsilon$ is bounded, and since continuous functions on compact sets are uniformly continuous, to show (iii), it is therefore enough to prove that f_n is continuous. By construction this is clear for (y, z) such that either $|z| < n$ or $|z| > n$. Let therefore $(\tilde{y}, \tilde{z}) \in [-R, R] \times \mathbb{R}^m$ such that $|\tilde{z}| = n$ be given. We have for $y \in [-R, R], z \in \mathbb{R}^m$

$$f_n(y, z) = \inf_{\hat{y} \in \overline{B_R(0)}, \hat{z} \in B_{\frac{2M}{\phi_n(|z|)}}(\begin{pmatrix} y \\ z \end{pmatrix})} \left\{ f(\hat{y}, \hat{z}) + \phi_n(|z|) \left| \begin{pmatrix} y \\ z \end{pmatrix} - \begin{pmatrix} \hat{y} \\ \hat{z} \end{pmatrix} \right| \right\},$$

hence

$$\inf_{\hat{y} \in \overline{B_R(0)}, \hat{z} \in B_{\frac{2M}{\phi_n(|z|)}}(\begin{pmatrix} y \\ z \end{pmatrix})} \{f(\hat{y}, \hat{z})\} \leq f_n(y, z),$$

and therefore by $\phi_n(|z|) \rightarrow \infty$ for $z \rightarrow \tilde{z}$ and (ii)

$$\begin{aligned} \liminf_{(y,z) \rightarrow (\tilde{y}, \tilde{z})} f_n(y, z) &\geq \liminf_{(y,z) \rightarrow (\tilde{y}, \tilde{z})} \inf_{\hat{y} \in \overline{B_R(0)}, \hat{z} \in B_{\frac{2M}{\phi_n(|z|)}}(\begin{pmatrix} y \\ z \end{pmatrix})} \{f(\hat{y}, \hat{z})\} = f(\tilde{y}, \tilde{z}) = f_n(\tilde{y}, \tilde{z}), \\ \limsup_{(y,z) \rightarrow (\tilde{y}, \tilde{z})} f_n(y, z) &\leq \limsup_{(y,z) \rightarrow (\tilde{y}, \tilde{z})} f(y, z) = f(\tilde{y}, \tilde{z}) = f_n(\tilde{y}, \tilde{z}). \end{aligned}$$

This obviously implies the continuity of f_n in (\tilde{y}, \tilde{z}) , and concludes the proof of (iii). \square
